JULY TO DECEMBER.

147867
28/12/18.

London :

PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION,
429, STRAND, W.C.

LIST OF ILLUSTRATIONS.

	PAGE		PAGE
SPECIAL PLATES.			
Death from Shell Shock (F. W. Mott) ...	Facing 614	Knee-joint, Results of Sixty Consecutive Cases of Wounds of (W. H. Ogilvie), 281 ...	281
Haemagglutinin Reaction as a Test of the Toxicity of Various Antiseptic Reagents (Colonel C. J. Bond) ...	Facing 751	Knee-joint, Treatment of Gunshot Wounds of (Captain C. Max Page) ...	285
Infective Jaundice (Sir Bertrand Dawson, Lieut.-Col. W. E. Hume, and S. P. Bedson) ...	Facing 346	Lead, Plain, and Antimonial Lead, Experiments on the Solubility of (T. Maltby Clague and A. J. Watson) ...	757
Pathological Findings in Injured Nerves (Captain Sydney M. Cone). Facing 615	Facing 615	Meningococcus of Weichselbaum (Edward C. Hort) ...	379
War Nephritis (Captain J. Shaw Dunn and Captain J. W. McNee). Facing 750	Facing 750	Misplaced and Missing Organs (Sir John Bland-Sutton) ...	607
		Myocardial Change, a Possible Sign of (S. Russell Wells and J. S. Goodall) ...	183
		Mesopotamia: Sketch Map ...	24
		Motor Cars run by Coal Gas ...	522
		Nasal Sinuses, Operations on, carried out through a Temporary Opening in the Septum (Trans-septal), (Norman Patterson) ...	514
		Operating Theatre, Field, Mechanical Aids in (Captain W. F. Bensted-Smith) ...	152
Blood Transfusion, Direct (Lieut.-Col. Alfred J. Hull) ...	683	Osteomyelitis, Acute, of the Frontal Bone (Herbert Tilley) ...	8
Bombing the Red Cross ...	502	Phalanges, Congenital Deficiency of (Elizabeth Sloan Chesser) ...	215
British Medical Women, Part Played by, in the War (Mary H. Frances Ivens) ...	204	Plastic Transcostal Thoracotomy (Captain E. M. Cowell) ...	581
Canadian Army Medical Service (Surgeon-General J. T. Fotheringham) ...	472	Pneumatic Tourniquet for Surgical Purposes ...	392
Carrel-Dakin Treatment and a Method for its Application on an Extensive Scale (Captain Lyn Dimond and Captain Robert McQueen) ...	387	Reamputation (Major W. A. Chapple) ...	242
Carrel's Tube, for Use especially where there is Danger of Pressure on Tissues, Modification of (Captain H. Driffield Levick) ...	762	Royal Army Medical Corps and its Work ...	217, 255
Clavicle, Apparatus for Treatment of Dislocation of Acromial End of ...	154	Salvarsan, Apparatus for Intravenous Injection of ...	119
Cranial Injuries in War, Treatment of (Captain J. Anderson) ...	44	Sand Sledge (Major W. Cameron Macaulay) ...	805
Dermatitis due to Explosives in Air Raids (J. H. Sequeira) ...	148	Scissors, Forceps, and Sponge-holder Combined ...	585
Enteric Stools, Method for Study of (Major F. B. Bowman) ...	250	Screen Method of Localization (Captain John H. B. Shaxby) ...	389
Fibroid Uterus Treated by X Rays (Florence A. Stoney) ...	723	Shell Casing Embedded in Orbit (Sir W. J. Collins) ...	245
Flapless Amputation (W. Sampson Handley) ...	246	Spirochaetes Occurring in the Urine of Cases of "Pyrexia of Unknown Origin" (Major S. W. Patterson) ...	418
Flavine, Fifty Cases Treated by (Captain E. F. Bashford, Captain J. N. J. Hartley, and Captain John T. Morrison) ...	851	Spontaneous Evacuation of a Shrapnel Bullet in the Lung by Expectoration (R. Murray Leslie) ...	649
Fracture of Femur, Compound, caused by Gunshot Wound, Early Treatment of (Captain E. C. Dun) ...	213	Splint for Treatment of Gunshot Wounds Involving the Shoulder Joint (Captain J. Campbell) ...	480
Gonorrhoeal Keratosis (Captain W. H. Brown and Captain A. M. Davidson) ...	453	Supination by Plaster (P. J. Verrall) ...	150
Gunshot Injuries of the Mandible, Treatment of (J. F. Colyer) ...	1	Syringe, Double-barrelled ...	392
Haemagglutinin Reaction as a Test for the Toxicity of Various Antiseptic Agents (Colonel C. J. Bond) ...	753	Thomas and Jones Splints: Adaptation of to Obtain Fixation of the Arm in an Abducted Position while the Patient is Ambulatory (Major Robert B. Osgood) ...	478
Herpes Zoster, Association of with Arsenic (Hildred Carlill) ...	9	Thomas Splint for Fractures of Femur (Captain W. Rankin) ...	248
India and Medical Progress (R. McCarrison) ...	110	Thomas's Splints: Some Reflections on (Lieut.-Col. J. Lynn Thomas) ...	175
Infected War Wounds, Treatment of (Rutherford Morison) ...	504	Thomson, John Roberts ...	405
Inguinal Hernia, Cure of (Lieut.-Colonel Alfred J. Hull) ...	549	Thyroid Gland in Health and Disease (Robert McCarrison) ...	291
Knee, Treatment of Cases of Septic Arthritis of (Captain W. Rankin) ...	288	Tourniquet, Modified Anchor ...	456
		Trench Fever, Etiology of (Captain Alwin M. Pappenheimer, Lieut. H. N. Vermilye, and Sgt. J. H. Mueller) ...	475
		Trench Nephritis (Lieut.-Col. J. Michell Clarke) ...	241

INDEX TO VOLUME II FOR 1917.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma, Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria and Sugar; Light, Roentgen, Radium, X Rays; Status Lymphaticus and Thymus; Eye, Ophthalmia and Vision; Bicycle and Cycle; Motor and Automobile; Association, Institution, and Society; Paris, France; Berlin, Prussia, Germany; Vienna, Austria, etc. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Correspondence," "Leading Articles," "Reviews," etc. Original Articles are indicated by the letter (O).

A.

ABBOTT, Captain William Norman, Military Cross conferred upon, 738
Abdominal wall, anterior, congenital absence of (H. C. Coxon), 425
Abdominal wound, faecal-smelling gas (Captain C. S. Staddon), 389
Abdulla Company's almanac, 815
ABRAHAM, Captain Everard Cecil, Military Cross conferred upon, 839
Absent colleagues, 699
Academy, Royal, of Medicine in Ireland: *Section of Medicine*—F. C. Purser: Shell shock, 81—Dr. Boxwell: Albuminuria due to salicylates, 784
Acetic acid commandeered by Ministry of Munitions, 450
Acetozone as a general surgical antiseptic (Lieut.-Colonel G. Gore-Gillon and R. T. Hewlett), 209. (O)
ACKROYD, Captain Harold, killed in action, 269—V.C. awarded to, 370—Estate of, 738
ACLAND, Major Hugh Thomas Dyke, C.M.G. conferred upon, 234
Acorns, peeled, analysis of (J. L. Baker and H. F. E. Hulton), 676
Acriflavine, antiseptic properties of (C. H. Browning, R. Gulbransen, and L. H. D. Thornton), 70. (O)
Acriflavine paste as a dressing for infected wounds (Colonel C. J. Bond), 6. (O) *See also* Flavine
ADAM, Lieut. Arthur Innes, killed in action, 371
ADAM, Captain George Min, Military Cross conferred upon, 463
ADAMI, Lieut.-Col. J. G.: Croonian lectures on adaptation and disease, 9 (O), 98, 200
ADAMS, Captain Fred.: Halazone for water sterilization, 184
ADAMS, Captain Robert, killed in action, 565
ADAMSON, H. G.: Dermatitis from explosives used in air raids, 45
Adaptation and disease (Lieut.-Col. J. G. Adami), 9. (O)—Leading article on, 18—Correspondence on, 63, 98, 165, 200
ADDIS, Captain William Robert, Military Cross conferred upon, 839
ADDISON, Rt. Hon. Christopher, sworn Minister of Reconstruction, 344—Health problems and reconstruction, 726
Addison's disease and the war, 834
Adenoids and tonsils, recurrence of, 400, 465, 539, 672, 707
Adipocere in the bodies of the drowned (Lieut. H. W. Bernard), 252
Admirals of the British Navy, 848
Adrenalin, action of, 440
Adrenals, review of books on, 12
Adrenals in war infections, 561
AFFLECK, Captain John Ernest, Military Cross conferred upon, 398
After three years: The medical services (leading article), 187
After War Problems, rev., 391
AGASSIZ, Captain Cuthbert Delaval, Military Cross conferred upon, 463

AIINGER, Captain W. B.: Combined scissors, forceps, and sponge-holder, 585
Air force medical service, proposed (parliamentary question), 665
Air raid, pathogenic germs in sweetmeats thrown by Austrians, 408
Air raids, dermatitis from explosives used in. *See* Dermatitis
Air war (leading article), 457—Correspondence on, 500, 540
AITKEN, Major James, dies on service, 194
AITKEN, John, obituary notice of, 375
AITKEN, Surgeon Robert: Case of congenital transposition of the heart, 425
AITKEN, Captain William, Military Cross conferred upon, 267
Albuminuria due to salicylates, 770, 784
ALCINDOR, John: Notification of Births Act, 710
Alcohol and war, 529
Alcoholic factor in insanity (H. M. Pollock), 397
ALEXANDER, Lieut. Alan Mansell, killed in action, 872
ALEXANDER, F. W., urges compulsory notification of ophthalmia neonatorum, 389
ALEXANDER, Colonel J. D., Belgian Order of Leopold conferred upon, 433
ALFORD, Lieut. Ernest Francis Remington, Military Cross conferred upon, 268
Aliens Restriction Order and hospital work, 493
ALLAN, F. J., elected Fellow, Royal Sanitary Institute, 847
ALLBUTT, Sir Clifford: Investigation of the significance of disorders and diseases of the heart in soldiers, 139. (O)—War Emergency Fund of the Royal Medical Benevolent Fund, 842
ALLEN, Captain William Barnsley, bar to Military Cross, 463
ALLINSON, Lieut. C. H., killed in action, 371
ALLWORTHY, Captain S. W.: Scabies problem on active service, 468
ALMON, Lieut. John Egan, killed in action, 702
ALSTON, Lieut.-Col. Ernest Alfred Brooke, killed in action, 302
ALSTON, Captain James, reported killed in action, 599—A correction, 737
ALSTON, Captain John, Military Cross conferred upon, 566—Killed in action, 599, 737
Alvarenga prize awarded, 586
Ambulance College, 496
Ambulance de l'Océan La Panne, Belgium: Publication of papers founded on the work of, 480
Ambulance in rest (Captain Andrew Macphail), 298
Amenorrhoea in war time, 734, 780
Americas. *See* United States
American Electrotherapeutic Association to form a unit for electrotherapeutic treatment, 170
American Fellowship in French Universities Society, 356
American Gynaecological Society, *Transactions*, rev., 253
American hospitals and surgeons in France, 763

American Laryngological Association, *Transactions*, rev., 12
American Red Cross. *See* Red Cross
Amoebic dysentery. *See* Dysentery
Amputation, flapless, with subcutaneous division of the bone at a higher level (Captain W. Sampson Handley), 244. (O)
Anaesthesia, practical methods of, 99
Anaesthetic, acetozone as (Lieut.-Col. G. Gore-Gillon and R. T. Hewlett), 209. (O)
Anaesthetics in military hospitals (Lieut.-Col. J. F. W. Silk), 618—Discussion, 619—Correspondence on, 710
Anaphylactic and pseudo-anaphylactic skin reactions, 264
Anaphylactic shock. *See* Shock
Anatomical nomenclature (leading article), 121—Correspondence on, 134
Anatomical and physiological principles *re* muscles, bones, and joints. *See* Muscles
Anatomy, Atlas of, rev., 620
Anatomy and statecraft, 491
ANDERSON, Lieut. David, dies on service, 434
ANDERSON, Elizabeth Garrett, obituary notice of, 844
ANDERSON, H. Graeme: Precautions for flying men, 124
ANDERSON, Captain J.: Treatment of cranial injuries in war, 42. (O)—Surgical treatment of severe penetrating wounds of the chest in a casualty clearing station, 575. (O)
ANDERSON, Captain Lewis, D.S.O. conferred upon, 398
ANDERSON, Louisa Garrett, Order of the British Empire conferred upon, 295
ANDERSON, Major W. H. K., Croix de Guerre conferred upon, 96
ANDERSON, Captain W. J., accidentally killed, 371
ANDERSON-BERRY, Captain David Douglas Anderson, killed in action, 630
ANDREWS, Deputy Surgeon-General Octavius W., Italian medal for military valour conferred upon, 702
Angina, Vincent's: Treatment of (Captain E. Emrys-Roberts), 360 (O)—Correspondence on, 404, 439, 469, 502, 570—Among the troops in France (Captain R. J. C. Douty), 685. (O)—A correction, 816
Anglo-Russian hospitals. *See* Hospitals
Animals, diseases of, report, 430
Animals, living, experiments on, 1916 report, 365
Annals of Medical History, 16
Annual Charities Register and Digest, rev., 362
Annual Representative Meeting (leading article), 156
Antimonial lead. *See* Lead
Antirabic treatment at the Paris Pasteur Institute, numbers, 360
Antiseptic, nasal, 125
Antiseptic properties of acriflavine. *See* Acriflavine
Antiseptic reagents (various), haemagglutinin reaction as a test of toxicity of (Colonel C. J. Bond), 751. (O)

Antiseptics of the chlorine group and acriflavine and other dyes, relative germicidal efficiency of (H. D. Dakin and E. K. Dunham), 641 (O).

Antiseptics, internal, combination of in treatment of dysentery, wounds, etc. (L. W. Seymour), 115.

Antiseptics, modern (Sir Alfred Pearce Gould), 577 (O).

Antitoxic serum, preparation of the skin for, 804, 848.

Antitoxin serum for gas gangrene, 308.

Apothecaries' Hall of Ireland: Information concerning the study of medicine, 324.

Apothecaries' Society of London: Pass lists, 136, 308, 569, 742—Information concerning the study of medicine, 319—New Master appointed, 501.

Appendix, State protection of, 873.

APPLEYARD, Major Sydney Vere, D.S.O. conferred upon, 702.

ARKLE, Captain J. S. (and others): Report on wound treatment by brilliant green paste, 506 (O).

ARMITAGE, Captain Frank Rhodes, killed in action, 269.

ARMSTRONG, Captain Arthur Chester, Military Cross conferred upon, 161.

ARMSTRONG, Captain Gordon Watson, D.S.O. conferred upon, 702.

ARMSTRONG, Major Forster, killed in action, 495.

ARMSTRONG-JONES, Sir Robert, appointed J. P. for County of London, 102.

Army, Austrian, venereal disease in, 300.

ARMY, BRITISH:

Army Medical Corps and hospital inspections, 804.

Army medical economies (leading article), 52—Correspondence on, 135.

Auxiliary R.A.M.C. Fund, 136, 604.

Enteric fever in (parliamentary question), 837.

Exchanges, 136, 237, 276, 303, 375, 440, 541, 570, 604, 635, 814, 876.

Gratuities of officers, R.A.M.C. Territorial, 276.

Half-pay for surgeon-generals, 876.

Information concerning the medical service of, 343.

Medical re-examination. See Medical.

Parliamentary questions, 160, 192, 231, 563, 627, 665, 735, 804, 837, 870.

Pay of, 563, 735.

Pay of junior officers, 870.

Pay of officers R.A.M.C. (Reserve), 274.

Pay of Special Reserve and Territorial officers, 404.

Promotion of army officers, 123.

Promotion in the R.A.M.C. Special Reserve, 274.

Royal Army Medical Corps and its work, 217, 254, 262, 306.

Small-pox in the army at home, 870.

Territorial *à la suite* officers, 19.

Territorial Decoration, 407, 814.

Territorial medical officer, wounded, 497.

Territorial medical officers, promotion of, 563.

Territorial and temporary officers R.A.M.C., 226.

Vote of thanks to, 595.

Week-end leave for military medical men, 804.

Army Council Instruction re classification of soldiers, 600; re medical students in the ranks, 769.

Army, French, health of, in Macedonia, 673.

Army, Indian, appointments, 501—Information concerning the medical service, 343—Note on, 90—Promotion, 32—Vote of thanks to, 595.

Army Medical Advisory Board (parliamentary question), 231.

Army Medical Department in the War Office, status of (parliamentary question), 193.

Army medical economies (leading article), 52—Correspondence on, 135, 236—Note on, 227.

Army medical re-examination. See Medical.

Army Medical Service administration (parliamentary question), 193.

Army Medical Service inquiry (leading article), 293—Committee appointed, 299, 368—Committee goes to France, 460—Parliamentary questions, 563, 627.

Army Medical Service in India, 90.

Army Medical Services in France (parliamentary question), 627, 655.

Army medical vote, 228.

Army recruiting. See Recruiting.

Army, United States, medical department of, 630—Transport and treatment of wounded, 629—Schools of instruction for army medical officers in America, 629—The Usacs, 629—High proportion of defective eyesight, bad teeth, flat foot, etc., among the new army, 728—Officers quartered in Dublin invited to use library of Royal College of Physicians of Ireland, 877.

ARNOLD, Lieut. Charles Vernon, dies on service, 269.

Arsenic, association of with herpes zoster (Hildred Carhill), 9 (O).

Arterial circulation, fragment of shell in (Captain C. S. O'Neill), 719 (O).

Arthritis of knee, septic, treatment of certain selected cases (Captain W. Rankin), 287 (O).

ARTHUR, Captain David, dies on service, 301.

ARTHUR, David (and John Muir): *Manual of Practical X-Ray Work*, rev., 455.

Artificial limbs, national experimental laboratory for, 398.

Artificial limbs, modern, and their influence upon methods of amputation (E. Muirhead Little), 550, 555 (O)—(Major R. C. Elmslie), 553 (O)—Discussion, 555.

Artificial limbs, renewal of (parliamentary question), 665.

Artificial respiration in treatment of haemothorax, 593.

ASCOUGH, Captain Matthew Thomas, Military Cross conferred upon, 839.

As others see us, 265.

ASPINALL, Captain W. R., killed in action, 255, 462.

Association, American, for control of syphilis, 52.

Association, American Medical, annual report, 68.

Association, British Dental, annual meeting, 179.

Association, British Hospitals, and treatment of wounded and disabled men in voluntary hospitals, 551.

Association, British Medical, Annual Representative Meeting (leading article) 156.

ASSOCIATION, BRITISH MEDICAL:

Dorset and West Hants Branch—Autumn meeting, 618—F. C. Forster: Neurasthenia and allied conditions, 618—Humphrey Davy: Certification of patients for asylum treatment, 618.

A NOTE ON THE TREATMENT OF GUNSHOT INJURIES OF THE MANDIBLE.

BY

J. F. COLYER, F.R.C.S., L.D.S.ENG.,

HONORARY CONSULTING DENTAL SURGEON, CROYDON WAR HOSPITAL.

GUNSHOT injuries of the mandible differ materially in their character from the fractures met with in civilian practice: in the latter there is seldom any loss of tissue, and the displacements which occur are due in part to muscular action, and in part to the direction of the line of fracture; in the former there is often considerable loss of tissue and comminution of the bone, with a corresponding increase in the displacement of the fragments. The problems to be faced in the treatment of the injuries are to a great extent new, and the treatment cannot altogether be carried out on the ideal lines suggested by those who have written on the subject, drawing their experience from civilian life. In treating these injuries the surgeon is perhaps too apt to lose sight of the utility of interdental splints; while the dental surgeon is too apt to lose sight of the facts that treatment is required beyond the mere adaptation of splints, and that sepsis is a factor in delaying and often preventing union.

The fractured mandible is a comparatively easy bone to treat if we remember that its pathology is very similar to that of the long bones, and that it calls for the same lines of treatment as those applicable to such bones, namely:

- (1) Control of the sepsis.
- (2) Approximation of the fractured ends.
- (3) Fixation of the parts.

Unfortunately, amongst the members of the dental profession there is considerable diversity of opinion on the question of treatment. There are those who consider that the best treatment is to adapt splints with the teeth in ideal occlusion, retaining the teeth even when intimately connected with the region of fracture. On the other hand, there is a smaller section which considers that the all-important factor is speedily to rid the parts of sepsis, and not to fix splints until the sepsis is thoroughly under control. The treatment at the Croydon War Hospital has always been carried out on these latter lines, and the experience gained shows conclusively that the former method of treatment, which ignores fundamental surgical principles, leads to considerable delay in union, and, in a large majority of instances, to non-union where union could reasonably be expected. I propose, therefore, briefly to record the methods adopted at the Croydon War Hospital.

I. THE REMOVAL OF SEPSIS.

This question mainly centres round the retention of the teeth in the region of the fracture. When the line of fracture passes through the socket of a tooth the periosteum of the root is detached and a pocket is formed, which becomes filled with septic matter. The periosteum covering that part of the root is entirely destroyed, and whenever this happens there is no possibility of the periosteum becoming reattached. The result is a permanent pocket, from which infection is constantly passing to the fractured area. The pulps of the teeth also become infected, and each pulp chamber becomes an added source of sepsis. The removal of the tooth or teeth eradicates this focus of infection.

All teeth in relation to the fractured area should be removed. Though this step is not considered necessary by many of those engaged in treating these fractured mandibles, yet results speak for themselves; in cases in which the teeth are removed the sepsis is rapidly eliminated, and healing follows quickly with but little necrosis; in cases where the teeth are retained the sepsis persists, the incidence of the necrosis is greater and union is prevented. Two cases may be quoted by way of contrast.

CASE I.

The patient was injured on October 19th, 1915; by a glancing shot on the anterior part of the mandible. When admitted to hospital on April 19th, 1916, the condition was as follows: The lower portion of the bone was extremely comminuted (see diagram, Fig. 1); there was a free discharge of pus between the first and second incisors, mobility of the fragments, and a sinus under the mandible at the entrance wound. There was no displacement. The teeth present were:

8	7	6	5	4	3	2	1		1	2	3	4	5	7	8	
8	7	6	5	4	3	2	1		1	2	3	4	5	6	7	8

On April 29th the sinus was opened and packed, and the following teeth were extracted:

2	1		1	2	3	4	5
---	---	--	---	---	---	---	---

A splint was adapted to the lower teeth. The sinus healed rapidly, and by the end of June union was obtained. At the

FIG. 1.—(a) Line of vertical fracture; (b) area of comminution.

end of July the muco-periosteum showed no signs of trouble, and the patient was returned to dépôt with a denture.

As a contrast to this case the following may be quoted:

CASE II.

A machine gun bullet struck the bone on the lower border of the mandible in the region of the left premolars, and passed in a slightly upward direction, emerging on the right side about three-quarters of an inch below and external to the angle of the

FIG. 2.—(a) Tissue lost; (b) area of extreme comminution; (c) area of moderate comminution.

month. The patient was injured on July 1st, and admitted July 15th. The condition of the bone is shown in the diagram, Fig. 2.

There was considerable induration of the soft tissues, a sinus was present under the chin, the pulse-rate was 102, and the temperature was 100.4° F. The bullet had carried away the

eight anterior teeth. On July 29th the following teeth were removed:

8 2 4 6 8
8 7 6 5 5

* Unerrupted.

The suppuration in the mouth rapidly disappeared, the fragments in the meantime being allowed to approximate. On August 19th a splint was adjusted, consisting of a vulcanite cap covering the lower gums attached to a metal cap splint on the upper teeth. By October 12th union was complete.

The damage to the bone by the retention of the septic teeth is, I am confident, not fully recognized by those who are adverse to their removal. The infected teeth lead to a progressive rarefying osteitis, and this is well seen in cases of simple fracture where the teeth have been retained.

The worst effects of the retention of the teeth in the fractured area are met with in comminuted fractures in the region of the angle where the fracture includes the molar teeth. In this area the swelling of the soft tissues increases the "stagnation areas" around the teeth and adds considerably to the sepsis. Many cases have come under observation in which splints have been adapted to the teeth left in the region of the fracture. The condition of these patients on admission is usually as follows: There is considerable swelling about the ramus with one or more discharging sinuses; the mouth can be opened only to a slight extent and the mucous membrane in the neighbourhood of the molars on the injured side is ulcerated. This last condition is caused partly by the constant friction of the swollen mucous membrane on the teeth and partly by the action of the toxins formed in the deep pocket which usually exists posterior to the last molar in the mandible.

The method adopted at Croydon in these cases is as follows:

1. The third molars on the injured side are removed to give free drainage.
2. The sinuses are constantly irrigated and the bone, if necrosed, is allowed to sequestrate before its removal is attempted.
3. The mandible is fixed by means of a metal Gunning splint.

The following may be quoted as a typical case:

CASE III.

A patient was injured July 1st, 1916, and admitted July 13th. A bullet had entered half an inch above the right ala of the nose and emerged just behind the angle of the mandible on the same side. There was a deep flesh wound at the point of exit; all the teeth, with the exception of the left third molars, were present; there was no malocclusion. The skiagram showed a severe comminuted fracture of the mandible and a fracture through the maxilla in the region of the molars.

The diagram (Fig. 3) will help to give an idea of the extent of

FIG. 3.—Shaded area denotes area of comminution and lost tissue.

injury to the mandible. The greater part of the ramus, as shown by the shaded area, was severely comminuted; the portion (a) was displaced backwards; there was a fracture running from the sigmoid notch downwards and backwards to the posterior border of the ramus; a thin layer of the posterior border (b) had escaped comminution.

FIG. 4.

By October 15th, when the occlusion of the teeth was as shown in Fig. 4.

The contrast between the retention and non-retention of the teeth is shown in the following cases:

CASE IV.

A fragment of shell struck the mandible behind the right angle. The patient was injured on September 11th, and admitted on October 2nd. The mandible had deviated slightly to the left; there was considerable swelling in the neighbourhood of the wound, with a sinus freely discharging pus. The skiagram showed extensive comminution of the ramus from the region of the angle to just below the sigmoid notch. The third molar communicated with the fracture. The second and third molars were removed, together with several fragments of necrosed bone. A metal Gunning splint was adjusted, but not fixed until the external sinus had healed. By the middle of February union was complete, and the teeth were in perfect occlusion.

In this case the removal of the teeth ridded the injured parts of an active focus of infection and permitted free drainage; if the teeth had been retained the greater part of the ramus would have been lost from necrosis.

The contrast to this method of treatment is shown in the following case:

CASE V.

A patient was injured by a bullet which entered near the angle of the mandible on the left side and emerged through the right cheek. He was wounded on November 13th, and on December 16th a splint was fixed in France. No teeth were removed. On April 5th he was admitted to Croydon in the following condition:

1. The left lower third molar was loose and lying in a horizontal position in the region of the fracture, the tooth being simply attached by its neck to the muco-periosteum.
2. There was a sequestrum about 1 in. in area which was present in the mouth. This was removed, and a skiagram taken, which showed a complete loss of the lower two-thirds of the ramus.

In this case the loss of tissue was almost certainly due to chronic sepsis fostered by the presence of the teeth. If the teeth had been removed at an early stage and the sepsis controlled, there is little doubt that union would have followed.

In my opinion, not only should the teeth in the area of fracture be removed, but the whole mouth should be freed of septic teeth; in other words, the dental sepsis should be radically treated. The benefits to the patient from the removal of the dental sepsis are:

(a) The wounded area heals more rapidly because it is not being constantly reinfected by the sepsis around the teeth.

(b) The removal of the dental sepsis leads to marked improvement in the general condition, and this in turn reacts on the wounded area.

At Croydon this free removal of dental sepsis has been carried out systematically, with the greatest benefit to the patients. The general standard of health has been excellent, and it was remarked by one who visited the hospital, and whose opinion was valued, that they were the healthiest collection of patients he had ever seen in any hospital. In but few cases is there loss of weight during the treatment, and this is remarkable considering that for a stretch of two and sometimes three months nothing but "slop diet" can be taken. The most striking evidence in support of the removal of sepsis is the almost complete absence of complications such as bronchopneumonia or intestinal affections.

II. THE APPROXIMATION OF THE FRAGMENTS.

To obtain osseous union it is essential that the fractured ends should be brought into contact, or that living bone should exist in the tissues between the gap in the bone. In the mandible the approximation of the fragments will result in narrowing of the arch and some loss of masticating area, but from a practical point of view the masticating area can be restored by properly constructed artificial dentures. Some writers, who place considerable stress on correct occlusion of the teeth, maintain that if the fractured ends are kept apart, fresh bone will eventually bridge the gap. There is nothing in pathological teaching or experience to support this view, and if bone cells do not exist in the tissues uniting the fragments it is difficult to see how the bone is to be created. The cases in which bone has been observed to form have probably been examples of comminution of the tissues with the fragments of bone remaining, and forming nuclei for bone growth. Experience shows that many of these cases end, as might be

expected, in fibrous union. The choice would therefore seem to lie between a mandible firmly united, capable of bearing the strain of an efficient denture, or the teeth in

FIG. 5.—Loss of tissue indicated by the darkened area.

correct occlusion on a base not capable of bearing the strain of mastication.

In the incisor region the fragments are allowed to approximate, provided the narrowing does not lead to marked deformity of the face and disorganization of the occlusion. An example may be quoted:

CASE VI.

The bullet carried away the bone, as shown in Fig. 5. The parts were approximated and osseous union followed with but slight interference with the occlusion of the teeth, as shown in Fig. 6.

FIG. 6.

In the premolar region, and especially the molar region, the following method is adopted: The upper teeth opposing the teeth of the posterior fragment are removed; this allows the posterior fragment to spring forwards and upwards, the anterior fragment being allowed to swing over to the injured side. In practice the following method is pursued:

Where the gap is small, the posterior fragment is released, and a splint made with the anterior fragment in position. Skiagrams are then obtained. If the bony parts are seen to be in contact, the splint is fixed in position; otherwise the anterior fragment is brought across until contact is obtained. The mandible is, therefore, in many cases mended with the anterior fragment swung over to the injured side. This is no disadvantage, because, with the removal of the splint, the mandible tends to readjust itself to functional activity, provided the so-called "bite of comfort" is avoided. This condition requires a word of explanation. In fractures about the region of the angle the ramus moves forwards and brings the soft tissues in contact with the upper teeth, but even if there is no loss of tissue, the soft tissues are considerably damaged, and when healing is complete there is a certain amount of permanent swelling, and a similar condition follows. The result is that the patient, in order to obtain a "bite of comfort," involuntarily brings the mandible over to the injured side, and the teeth are not in occlusion; further, in many cases definite ulceration of the soft tissue follows.

It is difficult to say what is the breadth of gap that can be satisfactorily reduced in this manner without causing undue deformity, but it probably varies in individual cases. Good results may be confidently anticipated where the gap is less than three-quarters of an inch, and even with gaps up to one inch approximation may prove successful in some cases. With a wider gap, approximation of the fragments must give way to bone grafts for the formation of an osseous bridge.

The following case may be quoted because it illustrates in an excellent manner: (1) The effects of the glancing shot on the bone; (2) the approximation of the fragments to obtain union; (3) fixation in a malposition; (4) readjustment of the mandible to functional activity.

CASE VII.

The patient was injured on August 18th, 1916, and admitted September 14th. The bullet entered one inch behind the left angle of the mandible, and emerged through the right side of the bone, about midway between the angle and the symphysis, and about midway between the lower border of the bone and the alveolar border.

On admission there was a sinus at the site of the exit wound;

there was a purulent discharge, and a probe passed up the sinus on to bare bone. The teeth present were:

7 6 5 4 3 2 1	1 2 3 4 5 6 7
7 6 5 4 3 2 1	1 2 3 4 5 6 7

The mouth was gagged open on the second molars. The skiagram showed loss of bone in the region of the first molar and a comminution of the bone extending backwards to the second molar and forwards to the incisors. The following teeth were removed:

8 7 6

8 7 6 5 4 3

* Unerupted.

The sinus was dilated, and a few fragments of necrosed bone were removed. The patient was then left to allow the fragments to approximate by natural means. The left fragment passed across to the right, and the right or posterior fragment swung forwards. A splint was adjusted to bring the left fragment still further to the right; this was fixed on October 5th, and by the end of January there was good union. At this period the teeth on the left side were not in occlusion, but the efforts of the patient to utilize the teeth soon resulted in these teeth assuming the correct occlusion.

III. FIXATION OF THE FRAGMENTS.

Many splints have been devised for the treatment of the fractured mandible. The most self-cleansing and the most reliable is the metal Gunning splint fixed in position with oxyphosphate of copper. Hooks, elastic bands, and wires only add to the difficulty of cleansing the mouth.

In conclusion, it may be said with confidence that if ordinary surgical principles are adopted in the treatment of gunshot injuries of the mandible, the most excellent results can be expected. To adapt splints in a "field of sepsis," as is so often done, is to ignore the most elementary surgical teaching.

A detailed account, fully illustrated, of the methods referred to in this paper was published in the *British Dental Journal*, March 15th, April 2nd, and April 16th, 1917.

THE DEPARTMENT OF ORAL SURGERY OF THE HARVARD SURGICAL UNIT.

BY

MAJOR V. H. KASANJIAN.

During the present war soldiers who have received wounds of the face and jaws have for the first time been collected in centres for treatment. This concentration has made it possible to systematize and simplify certain phases of the work and to form definite conclusions as to the cause and treatment of certain complications.

Some of the advantages have been:

The nursing staff is more efficient as they become familiar with and devote their entire attention to the care of fractured jaws. The daily care and feeding have been organized to make easier the treatment of a large number of patients.

The development of a mechanical laboratory has made it possible to apply at an early date the splints and appliances which are essential to successful treatment.

The treatment of cases during a period of over eighteen months has given opportunity to maintain a comprehensive system of records from which deductions can be made on the complications, mortality, etc.

Daily Care of the Patient.

Cases are admitted to the department usually from two to three days after injury. They are suffering from mental shock, toxic absorption from the wounds, and from lack of nourishment owing to the inflammation of the soft tissues and the derangement of the organs of mastication.

The mouth is irrigated at frequent intervals during the day and night, in most cases every two hours, and in addition the mucous surfaces are swabbed with cotton pledgets saturated in tincture of iodine or hydrogen peroxide, to remove mechanically mucous deposits and adherent food particles.

The majority of operations are performed under a local anaesthetic. This procedure makes it possible to remove foreign bodies, fragments of teeth or roots, and detached segments of bone. The suppuration or necrosis during the early stages of treatment is thus materially reduced.

Immobilization of the Maxillary Bones.

We believe that early immobilization of maxillary fractures means the quickest and most satisfactory recovery. While technical difficulties may stand in the way, since nearly every splint must be made to suit each individual case, we have devoted considerable attention to the classification of the type of splints, and the simplification of their preparation. A number of devices of a simple and temporary nature have been designed to immobilize the jaws during severe illness, and until more permanent splints can be employed.

For cases of ordinary severity, the usual splints (with or without modifications) familiar to the oral surgeon are used. In many cases of extensive destruction of hard and soft tissues it was found that intraoral splints were inadequate, and an external support, consisting of a series of vulcanite plates fitted over the forehead, with a head-gear of straps, was developed. With this appliance as a base, the tissues of the mouth, nose, eyes, and neck are under control, either during the process of scar contraction or after plastic operations.

In the many cases of extensive loss of the mandible accompanied by laceration of the lower part of the face and neck, a sectional or folding artificial jaw has been successfully used; it acts as a framework for plastic operations, is easily removed, and at the same time maintains the contour of the lower part of the face.

In restoring the upper jaw, a satisfactory means of retention and also of resistance to the force of mastication has been designed, and in cases in which the loss of the mandible has been sufficiently extensive to destroy the function of the temporo-mandibular joint, a mechanical condyle has been substituted.

Septic Complications.

The special septic complications, apart from the usual condition of local sepsis in the wound, which have been observed, are septicaemia, cellulitis, and bronchopneumonia. No cases of pyaemia have occurred.

Septicaemia.—There have been two cases of septicaemia, both ending fatally. In each the wounds of entry and exit were small. In one there was a scarlatiniform rash and the infection was thought to be streptococcal, but no blood cultures were made. In the other, growths of a bacillus were obtained from samples of blood taken on two successive days. The bacillus was not identified, as it died off in all the subcultures.

Cellulitis.—A form of cellulitis spreading from the wound over the face and scalp has been observed in several instances. It was accompanied by pyrexia, but in no case did the patient seem very ill or suffer from any serious consequences. The affected area of skin has been light pink in colour, slightly tender, with a definite induration at the spreading margin. These cases have been regarded as mild erysipelas, and have been treated as such. In some instances the condition has recurred in the same patient.

Bronchopneumonia.—This has been one of the most fatal complications. Preliminary septic bronchitis has occurred in some cases; in others the onset of pneumonia has been sudden. Empyema and multiple abscesses in the lung have been common, and the mortality has been high. The pulmonary infection seems to be attributable, as a rule, to the inhalation of septic material from the mouth, and a high percentage of the cases has followed general anaesthesia. Many patients were suffering from bronchopneumonia at the time of their admission, and it was usually found that they had already been operated upon elsewhere under general anaesthesia.

Value of Local Anaesthesia.

Our practice now is to employ local anaesthesia whenever this is possible for operation upon patients with wounds which communicate with the mouth. If general anaesthesia is necessary, special precautions are taken to prevent the entry of septic material into the air passages. These precautions are as follows:

1. A hypodermic injection of a hundredth of a grain of atropin is given one hour before operation in order to reduce the secretion of saliva.
2. The mouth is carefully cleaned by swabbing and syringing immediately before the operation is commenced.
3. The administration of the anaesthetic is commenced in the ordinary way. As soon, however, as the patient is unconscious,

and before he has lost his reflexes, nasal tubes are passed through the nostrils into the pharynx, and the administration is continued through them while the buccal cavity is well packed with dry gauze, so as to prevent the backward escape of blood and other fluids.

Those who are working at clearing stations and other points where men with gunshot wounds involving the mouth receive treatment before reaching the base should always bear in mind the great danger of giving general anaesthetics to these patients.

Plastic Operations.

So far as concerns the soft tissues, these may be considered under the following headings:

1. *Primary Suture.*—There does not appear to be much scope for primary suture of gunshot wounds complicated by fracture of the jaw, for reasons which are manifest. However, so long as general anaesthesia is not employed, some advantage may follow accurate primary suture of those portions of a wound which involve the lip margins, the eyelids, the alae of the nose, portions of the external ears, or the outlying tributaries of a radiating wound, provided such suturing is limited, and no attempt is made to close the entire wound.

2. *Secondary Suture.*—Early secondary suturing has been increasingly employed of late. The interval that has been allowed to elapse between the infliction of the wound and its complete or partial closure has varied with the condition of local sepsis, but has most often been between the fifth and twelfth days. B.I.P. has been used as an adjuvant in these operations, we think with advantage. The use of early secondary suturing has done much to lessen the amount of deformity from scarring.

3. *Flap Operations.*—Although primary or early secondary suturing may be practised with success in some cases, yet extensive operations required for reconstruction of the face to cover deficiencies which have been brought about by actual destruction of tissue, or by scarring and laceration, are invariably postponed until all suppuration has disappeared. Primary or early secondary suturing may have served to bring the edges of a lacerated wound into apposition, or suturing may have been done at a later date to extend mucous surfaces or to lessen the deformity as a preparatory measure for an extensive plastic operation. In other words, in the first instance the suturing reduces the size of a wound in which there is no loss of substance, and in the second instance it lessens the area to be covered by flaps. In all cases in which there is an appreciable loss of substance and a plastic operation is contemplated, an appliance to reproduce the bony tissue is always made to serve as a framework, to give a natural contour to the soft tissues of the face or neck, and to prevent undue scar contraction.

Even for extensive plastic operations local anaesthesia is almost invariably used, because the majority of patients prefer it to a general anaesthetic, whilst from the operator's point of view it is better because he can take his own time to obtain juxtaposition of the flaps, the loss of blood is much less, the patient is quiet and under perfect control, and the dangers of a prolonged operation are reduced to a minimum.

Haemorrhage.

Among 400 cases of gunshot wound of the face with fracture of the upper or lower jaw treated in this department there have been 34 cases of secondary haemorrhage (8.5 per cent.), and of these 7 were fatal.

Injury of one or both lingual arteries in the floor of the mouth has been the chief cause of serious bleeding. In the majority of cases it has not been possible to secure the bleeding point, and proximal ligation has been employed. This, however, has not always been satisfactory, as it is often impossible to identify with certainty the vessel which is bleeding. Efforts to overcome this uncertainty by ligating the external carotid artery were not encouraging. Owing to the dropping of the fractured jaw and other anatomical and pathological derangements, the external carotid is not easy to find and ligate in these cases, the operation is somewhat prolonged and has a high mortality; moreover, concomitant injury of both linguals is not uncommon, in which event ligation of one external carotid is not sufficient. Recently we have had better results by direct ligation of one or both lingual arteries whenever

the anatomy of the wound was indicative of injury of these vessels.

Haemorrhages from—		No. of Ligations.	Deaths.
Facial artery (or branches)	7	{ Under local anaesthesia Under general ..	5 2 } 0
Nasal region	4	—	—
Lingual or inferior dental	21	{ Lingual External carotid ... Common carotid ...	6 9 4 } 1 2 3
Pharyngeal region ...	3	—	1*
Totals	34	—	26 } 7

* Suddenly.

The above figures are compiled from the records of the first 400 cases of gunshot wound of face and jaw treated in the department.

The total of cases of haemorrhage is 34 and not 35, since one patient had haemorrhage distinctly from both the nasal and the pharyngeal regions. One death occurred immediately following haemorrhage from the pharyngeal region before any assistance could be given. One case died from shock within a few hours after ligation of both lingual arteries. Of the five remaining cases which ended fatally, one died from recurrence of bleeding from the floor of the mouth and another from cerebral embolism. The three fatal cases from ligation of the common carotid had all previously had the external carotid ligated, but owing to a recurrence of haemorrhage the former artery was ligated as a last resort.

Mortality.

Of 436 recorded cases of injuries to the face and jaws treated in the department between July, 1915, and January, 1917, 19 patients died from the following causes:

Haemorrhage	7
Bronchopneumonia	5
Cerebral complications	4
Septicaemia	2
Collapse	1

It is hard to make an accurate analysis of the percentage of deaths among patients suffering from gunshot wound of the face and jaw, because wounds of other parts of the body may exist which are of more serious consequence than those of the jaw. Of the four cases which died from cerebral complications, three were suffering from fracture of the base of the skull and one from spinal injury in addition to the jaw-wounds.

Most of the patients who succumbed to bronchopneumonia had contracted this complication previous to admission to the department.

CONCLUSIONS.

We feel that some of the advances have been:

1. A realization of the importance of immobilization or reduction of maxillary fractures at the first possible moment along the lines of normal occlusion of the teeth.
2. Early reduction of sepsis by small and timely operations with a local anaesthetic.
3. A better understanding of the dangers attending the use of general anaesthetics for operations on patients suffering from face and jaw injuries.
4. The control of severe complications, especially of secondary haemorrhage.
5. The modification and simplification of many types of oral splints.
6. Temporary and permanent oral restorations.
7. The use of local anaesthesia for extensive plastic operations about the face, mouth, and neck.

This summary of the work has not included an appreciable number of cases which have been treated from necessity in other hospitals, nor a large number of patients who have received attention for dental and oral complications.

DR. LUDWIG LAZARUS ZAMENHOF, the inventor of the international language known as Esperanto, who died recently, was a member of the medical profession. He was born in 1859 at Byalistok, Grodno, in Russia, and practised as an ophthalmic surgeon in Warsaw. Esperanto was presented to the world in 1887.

A NOTE ON ORAL SURGERY.

BY

MAJOR A. C. VALADIER, C.M.G., R.A.M.C.,

AND

CAPTAIN H. LAWSON WHALE, R.A.M.C.

THE advances in the surgery of the jaw and face have been gradual, but as the result of experience a few points have crystallized out with distinctness.

At the beginning of the war broken fragments of bone were removed too freely; many such if left would have thrown out callus. A tooth should never be removed if there is any chance of it subsequently forming a useful support for dentures or other appliances. Even in the line of fracture the extraction of a tooth may be left until later, since for the period immediately following injury it may provide an invaluable *point d'appui* for some appliance.

Maxilla.

If the tuberosity carrying a molar tooth be separated from the rest of the bone by fracture, but the muco-periosteum is continuous, it should never be removed. It may be kept in position by any convenient method, whether by splint or by silk stitches through its muco-periosteum; and it will always unite with the parent bone. In the case of transverse fracture through both maxillae (with or without fracture of the palate), producing a downward sag of the maxillae *en masse*, the whole may be lifted up by a vulcanite plate moulded to the roof of the mouth; from the sides of this plate brass rods fitted with hooks permit of a constant pull by means of bandages fixed over the head. Union is established in less than three weeks. These two statements as to fractures of the maxillae are emphasized as being invariably true.

Mandible.

The displacement of fragments in a complete fracture of a ramus is often obstinate, and suitable neither for wiring nor, if there be a gap, for subsequent bone grafting. Occlusion of teeth in this very frequent type of case is obtained by building up the depressed side with vulcanite or a metal gutter, on which are fixed teeth.

Injury of Facial Nerve.

Often the loss of soft parts has involved a great part of the facial nerve, and on the injured side the angle of the mouth maintains its original relation to the lower jaw—that is, it is depressed. The tissue of the cheek is cicatricial, and anastomosis of the nerve is impracticable. A good result is obtained by elevating the mouth angle by a plastic operation.

Closure of Wounds.

A wound, however fetid, anywhere in the neighbourhood of the jaw ramus, should be closed as soon as possible. For drainage by tube a median stab-wound is then made beneath the chin.

Formation of Flaps.

Where a large gap in the cheek has to be covered by sliding a flap from one or both edges of the wound, the large amount of undercutting necessitated tends to impair vitality, and in particular to raise the tension on the stitches. To avoid these drawbacks the first third of the undercutting may be of dermis only; the next third may include fat and subcutaneous tissue; and the last third—that is to say, the most proximal part of the flap—may also embrace deep fascia. On pulling the flap in the necessary direction its deep surface now becomes shaped like a staircase; the blood supply is cut off to a less extent, and the tension is more diffusely distributed.

GENERAL CONCLUSION.

Speaking generally of facial wounds, it is advisable to delay considerably before doing final and finishing operations, but not at all before the primary sewing up.

The most common serious sequelae of war injuries to the jaw have been recurrent and secondary haemorrhages, inhalation pneumonia and gangrene of the lung, and mediastinitis.

Down to January, 1917, we had among 1,010 cases twenty-seven deaths, seven of these from pneumonia.

There were three tracheotomies (including one emergency laryngotomy) and eleven haemorrhages necessitating ligation of the external, and three of the common carotid. These three latter are all living, and apparently not suffering any discomforts as a consequence of this operation.

NOTE ON FLAVINE, SODIUM DESOXYCHOLATE, AND QUININE AS A MOUTH-WASH.

BY

F. M. WELLS, MAJOR C.A.D.C.

(From the Canadian Army Dental Corps Laboratory, London, S.W.)

In the estimation of the value of chemical substances at present employed as antiseptics in the mouth and throat there is a sharp division of opinion as to the advisability of employing antiseptics in the treatment of infections where the chemical is brought in contact with such a delicate structure as the mucous membrane. Any chemical which would act as a bactericidal agent, which at the same time would not destroy the life of cells and inhibit phagocytosis, and which could be applied to such a delicate surface as the mucous membrane without causing an irritant action, would satisfy a long-felt want in mouth and throat treatment.

I have in the course of the last ten months examined a series of substances comprising the principal antiseptics, washes, lozenges, pastilles, etc., in common use.

Neufeld has shown that bile salts have a solvent action on pneumococci, but not on other bacteria. Bile salts also dissolve completely leucocytes, spermatozoa, amoebae, spirochaetes, and trypanosomes.¹ Mair has brought evidence to show that scarlet fever is due to a pneumococcus-like organism which is also bile-soluble,² and has indicated that there is reason to believe that "trench nephritis" is due to a similar bile-soluble diplococcus. Mair found that the solvent action on pneumococci of sodium desoxycholate was ten times as powerful as sodium cholate or the commercial sodium taurocholate.³

These bile-soluble diplococci show also a special sensitivity to solutions of quinine, and there is evidence that a combination of desoxycholate and quinine has a much greater bactericidal effect on them than can be accounted for by a mere summation effect.

A solution with the following formula:

Quinine hydrochloride	5 grams.
Sodium desoxycholate	40 "
Glycerin	250 c.cm.
Water	to 1,000 "

has been in use in the form of a fine spray for the throat and nose in cases of scarlet fever for some months, with results so far satisfactory that they show that the treatment does no harm, and that septic throats clear up with it at least as rapidly as with any other form of treatment.

Messrs. Allen and Hanburys are now preparing tablets containing:

Sod. desoxycholate	gr. 1
Quin. ethyl. carb.	gr. 4
Ol. menth. pip.	m. 5
Glycerrhiz. ammon.	gr. 2

Also with flavine 1 in 1,000.

The quinine desoxycholate solution has a considerable bactericidal effect also on other cocci which are not bile-soluble, and in the strength used it appears to have no irritant effect on the mucous membrane.

The method employed to test the value of the preparations checking the development of bacteria were all carried out in the same mouth; only one test was made in twenty-four hours. The mouth was first rinsed thoroughly with distilled water, and after thirty minutes the saliva was expectorated from the mouth into a sterile test tube, and then a loopful inoculated into nutrient agar and plated. At the end of an hour another test was made in the same manner. These tests were used as controls. Immediately after the second control the substance to be tested was rinsed thoroughly over the mouth, and then tests made in the same manner every half-hour up to the fourth hour. Plates were incubated for twenty-four hours

and counts made. The most favourable results were obtained from a solution containing:

Desoxycholate	2 per cent.
Quinine	0.25 per cent.
Flavine 1 in 2,000.	

Judging from the chemical action of the desoxycholate and quinine tablet, it should be an excellent treatment for infected throats, as in the strength used in these tablets all the pneumococci strains are easily destroyed without causing any irritation on the mucous membrane. This pathogenic group alone is giving more trouble than any other strains to be found in the mouth and throat. Again, amoebae are very easily cleared out of the mouth with sodium desoxycholate and quinine in the strength used in these tablets, as I have found in cases of pyorrhoea caused by amoebae.

In the solutions containing desoxycholate and quinine and flavine the bacterial count, even after four hours, was in most cases considerably lower than the control before treatment, whereas with the more irritating antiseptic solutions the count rises rapidly after the initial fall until it reaches a figure in excess of the normal. I consider this secondary rise in the number of bacteria to be a useful indication of an irritant effect on the mucous membrane. The same difference is seen in comparing the effects of the 1 per cent. carbolic and the desoxycholate and quinine tablets. The latter do not show the same reduction in the number of bacteria as the corresponding solutions, possibly because the effect in the mouth is somewhat localized. At the same time the effect on the throat of the slowly dissolving tablet should be greater than that of a mouth-wash, as the swallowing of the saliva in which the tablet has dissolved keeps up a continuous action on the mucous membrane of the throat.

ACRIFLAVINE PASTE AS A DRESSING FOR INFECTED WOUNDS.

BY

C. J. BOND, F.R.C.S., HON. COLONEL R.A.M.C.(T.),

HONORARY CONSULTING SURGEON, NORTHERN COMMAND; MEMBER OF THE MEDICAL RESEARCH COMMITTEE; HONORARY CONSULTING SURGEON TO THE LEICESTER ROYAL INFIRMARY.

Owing to the limited supply of acriflavine we have been using this reagent at Leicester in the form of a cream or paste, somewhat on the lines of the B.I.P. method recommended by Rutherford Morison, which has given good results in certain cases. Thorough and efficient surgical treatment of the wound is still a necessary preliminary, but the results so far obtained with acriflavine paste as an adjunct to such surgical treatment are sufficiently encouraging to justify a wider trial.

I speak of such injuries as lacerated wounds of soft tissues, compound fractures of limb bones, and of septic cavities in bones associated with osteomyelitis, which often resist repeated efforts at sterilization by scraping out, and the removal of foreign bodies and bony sequestra. It is these heavily infected, profusely suppurating wounds as we see them at the base hospitals that seem to be especially benefited by packing with acriflavine paste after preliminary surgical sterilization and drainage. Amputation wounds have also been treated by leaving a quantity of the antiseptic material between the lightly sutured flaps where the amputation has had to be carried through infected tissues.

Several different forms of cream or paste have been tried:

1. Acriflavine soap paste is made by neutralizing stearic acid with sodium carbonate in the proportion of 1 part of sodium carbonate to $1\frac{1}{2}$ parts of stearic acid with the addition of 0.1 per cent. of acriflavine. The soapy compound so prepared is canary yellow in colour and firm in consistence.

2. Acriflavine gelatine is made by heating French gelatine in water with the addition of acriflavine 0.1 per cent. The consistence of the jelly is determined by the amount of water added.

3. Acriflavine starch mucilage is made by adding boiling water to starch with the addition of 0.1 per cent. of acriflavine; one part of starch to 10 of water forms when cold a thick mucilage. This form of dressing has been found useful for large granulating surfaces, such as flush amputation stumps, in which the absence of sticking is very helpful.

Of these the acriflavine stearate soap paste has been chiefly used so far, and may possibly be increased in antiseptic strength with advantage. No doubt a better basis in which to incorporate the antiseptic will be devised. It will be useful to say a word about the results from the clinical and bacteriological points of view.

Clinically.

The wound is first surgically cleansed, and if highly infected may be dried and swabbed out with acriflavine spirit or water solution and is then packed with the acriflavine paste. It is either left open with a top dressing of acriflavine gauze or it is closed by suture partly or entirely. If there are grounds for thinking that the infection may be inhibited by the antiseptic paste, aided by the preliminary mechanical sterilization, and especially if the state of the surrounding tissues will allow of coaptation of the sides of the wound without undue tension, it is closed. A wound so treated when examined two or three days later should, if progressing favourably, show an absence of any inflammatory peripheral zone, though there may be some slight redness and swelling about the skin edges and suture lines; there should be an absence of general malaise or evidence of toxic absorption. The cavity of the wound will contain a quantity of the canary yellow creamy substance, some of which will have exuded on to the gauze. In favourable circumstances—as, for instance, in the case of a cavity left in the head of a tibia after the removal of a shrapnel bullet with the debris of an abscess cavity and a quantity of bone—suture of the skin over the cavity so packed resulted in primary union of the soft parts, and the gradual consolidation of the bony cavity beneath. In other cases, where closure of the soft parts by suture has not been possible or only partially successful, time has been gained by reduction in the size of the wound. Where a wound so packed has been left open it can be refilled with the acriflavine paste at subsequent dressings, or irrigation with the watery solution and plugging with acriflavine gauze may be used. A considerable number of wounds have been treated with the paste, and while only a limited number have been so circumstanced in regard to the condition of the tissues and the arrest of the infection as to close primarily under one application of the paste, yet quite a number have improved during treatment, and post-operation flares, if present, have been less violent.

Bacteriologically.

It seems clear that, as in the case of B.I.P., wounds packed with acriflavine paste or soap are not sterilized in the bacteriological sense. Clinically the infection is inhibited or arrested, but organisms are still found in the discharge from the wound. There are, however, certain encouraging facts about the canary yellow coloured pus which collects in, or oozes from, such wounds when not closed. In the first place there is distinct evidence that many of the cells are living phagocytes and not dead pus cells; thus:

(a) If a drop of such pus be examined on a slide in normal saline with the addition of 1 per cent. watery iodine solution, a considerable number of the cells will show the mauve-coloured iodophil exudation which I have already described¹ as a delicate indication of functional activity in leucocytes. Dry films showing the same glycogen reaction may be fixed and stained in iodine vapour and mounted in iodine gum.

(b) A little powdered carmine is mixed with a drop or two of pus from the wound, thinned, if necessary, with normal saline. This is incubated for an hour in a plasticine cell. After the removal of the plasticine the incubated cells are examined in normal saline and 1 per cent. watery iodine solution. A number of the cells will have ingested the carmine grains.

(c) A dry film of the same pus from a wound in which the virulence of the infection had been inhibited by the

acriflavine paste, when stained with carbol. methylene blue gave evidence of active phagocytosis by the polymorph leucocytes, many of which contained cocci.

These three tests, each confirmatory of the others, may be used to test the relative non-toxicity to leucocytes of acriflavine, Dakin's solution, B.I.P., or any other antiseptic. Non-toxicity to phagocytes is of equal importance with bactericidal capacity in antiseptic reagents, and the relative non-toxicity of acriflavine is a matter of great importance.

I have already drawn attention² to the fact that sterilized rice starch grains previously mixed with B.I.P. are taken up by some of the leucocytes in a wound packed with that substance, but these starch grains so ingested, together with other free grains, are colourless and not blue. It has been suggested, probably rightly, that the absence of any iodine starch reaction in a wound treated with B.I.P. previously mixed with starch is due to the fact that the protein substances, either bacterial or leucocytic, seize upon the nascent iodine and prevent it reaching the starch grains. It is interesting to find that phagocytes from wounds dressed with acriflavine starch emulsion also ingest starch freely, though there can be no question of iodine action in this case.

From what I have seen of wounds treated by acriflavine in the casualty clearing stations in France and the base hospitals in England I think it will be found that a strength of 1 in 2,000 watery solution is better than a stronger solution for continuous application. How far the method of paste application is suitable for fresh wounds after initial surgical sterilization must be a matter for trial at the front. The non-toxicity of acriflavine, both local and general, seems however to be a point in its favour. It also does not give a shadow with x rays when the paste is packed in a wound.

Doubtless some surgeons who begin by applying acriflavine either in watery solution or as a paste to the surfaces only of infected wounds without efficient surgical sterilization will be disappointed with the results, for acriflavine, like all other antiseptic applications, will not reach the recesses of wounds when applied to the surface only; the reagent must be conveyed to the deepest parts, as Dakin's solution is conveyed by Carrel's tubes, or it must be applied thoroughly by the surgeon when the wound is freely exposed under an anaesthetic. Chemical sterilization must be the handmaid of surgery, and cannot take the place of drainage and mechanical sterilization by surgical means.

ACUTE OSTEOMYELITIS OF THE FRONTAL BONE: OPERATION: RECOVERY.

BY

HERBERT TILLEY, B.S., F.R.C.S.,

SURGEON, EAR AND THROAT DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL, LONDON.

THE gravity of this condition is so well known to and dreaded by those who are familiar with the surgery of the nasal accessory cavities that no excuse is necessary for bringing forward a case in which recovery took place. I will only anticipate by saying that the outlook of the patient was as bad as could be, that surgical intervention was adopted almost as a forlorn hope, and that the pluck and cheerfulness of the sufferer was one of the outstanding and bright features of an otherwise anxious and distressful situation.

History.

Mrs. T., aged 35, was taken ill with "influenza" during the first ten days of September of 1916. She suffered from intense pain in and around the left eye, and over the left frontal region. The temperature had varied from 99° to 100° in the morning to 103° to 104° at night.

I saw her at her home in Surrey on the evening of September 10th, and noted the following conditions: The left upper eyelid was intensely red and oedematous so that she could not open the eye. Chemosis of the conjunctiva in its outer half. There was slight oedema over the region of the left frontal sinus, and it extended outwards to the parotid region, over the left malar region, and as far downwards as the left angle of the jaw; but none of these regions were congested, and hence they were in striking contrast with the hyperaemia and oedema of the left upper eyelid. Deep pressure over the region of the frontal sinus

and lower half of the frontal bone was very painful. The mucous membrane of the left nasal cavity was swollen, deeply injected, and pus was visible in the anterior cleft of the middle meatus. The appearances in the right nasal cavity were normal.

The patient complained of dull headache, there was no vomiting, the pulse was 94, and her temperature was 102.4°.

It was obvious that the patient had an acute suppurative inflammation of the frontal sinus, and arrangements were made to bring her by motor to London next day.

Operation.

On September 11th, at 5 p.m., I opened the frontal sinus through an incision immediately below the line of the eyebrow, and terminating internally just above the internal canthus. On elevating a small disc of bone from the anterior wall of the sinus pus and air bubbles escaped. The whole anterior wall was removed; it was red, soft, and infiltrated with pus. The mucous membrane was intensely oedematous, and was wiped out—not curetted—with small gauze swabs. It was now seen that small points of pus made their appearance in the diploë spaces, which had been exposed on the boundaries of the sinus cavity, and I was forced to the doleful conclusion that osteomyelitis of the frontal bone had commenced, and that probably our intervention would prove to be "too late."

A loose wick of gauze was placed in the sinus, fomentations applied, and the patient returned to bed.

After-History.

The following are the chief points in the after-history and treatment of the illness:

September 13th. Some oedema of right upper and lower eyelids noticed. Free discharge of pus from the left frontal sinus and considerable oedema of fronto-parietal region. Oedema of left eyelid remains as before operation, and there is considerable proptosis of the eye.

September 18th. Opened an abscess in the orbit and evacuated 2 drachms of pus. Oedema of fronto-parietal region remains the same and free discharge of pus from the original incision in the eyebrow continues.

Since the first operation on the sinus this has been irrigated morning and evening with normal saline and hydrogen peroxide solutions, and it was possible to pass the cannula between periosteum and bone as far as the hair line—that is, as far as the oedema of the soft parts extended. In spite of the gravity of the local condition the temperature never rose above 100°, but usually attained that degree in the evening. Headaches were frequent, but were controlled by a combination of aspirin, salicylate of quinine, and codeia. The patient was cheerful, her mental condition remained good, and she took her food and slept fairly well.

Bacteriology.—The organisms found in the pus at the first operation were *Staphylococcus aureus*. There is also a small number of Gram-negative bacilli of coliform type. These, however, are relatively insignificant. Both organisms have been obtained in pure culture. No vaccines were used.

October 5th. During the past two or three days a painful swelling has appeared in the left breast. To-day, under local anaesthesia, I evacuated 4 drachms of thick greenish-yellow pus. This complication seemed to forebode evil and the possibility of further dissemination of infection, but the mammary abscess quickly healed and our fears proved to be groundless.

Time went on, and in spite of twice-daily irrigations of the sinus and of the subperiosteal cavity over the left frontal bone, the discharge of pus remained very profuse; the patient was not making headway, her sleep was not restful, and she was losing flesh.

Her husband was summoned from France and the pros and cons of an extensive operation for removal of the affected region of the frontal bone laid before him. He assented to this proposition, which was shared by Dr. Lack and myself.

October 23rd. A median incision was made in the forehead from the line of the hair to the inner end of the original incision in the eyebrow and a transverse incision from the upper end of the first and beyond the hair line to the temporal region. The scalp was turned outwards, and revealed a sad state of affairs.* The whole of the left frontal bone presented an inflamed and partially necrosed condition. Loose portions of bone were

removed, and in two places the adherent and inflamed dura mater came away with the bone, together with subjacent cortical substance of the brain. As much of the infiltrated and necrosed bone was removed as seemed advisable. A curved and multi-perforated drainage tube was placed around the borders of the bone wound and the scalp replaced and sutured in position. Fomentations were applied four-hourly for three days, and then replaced by ordinary dry dressings.

The patient made a rapid recovery, and returned home under the care of her local medical attendant on November 4th.

Three weeks later I was called down to see her, and found she was suffering from an acute attack of facial erysipelas, which had started from the internal angle of the original incision over the sinus. Once more she made an uninterrupted but somewhat slow recovery. Since then I have removed one or two small sequestra which have worked their way down to the incision in the eyebrow, but the patient is now well and the picture of good health.

REMARKS.

1. In my own personal experience this is the only case of acute osteomyelitis of the frontal bone complicating acute frontal sinus suppuration that I have seen recover, although I know that a few others have been recorded—for

example, one patient was shown by Mr. Mollison at the Laryngological Section, Royal Society of Medicine, May, 1917, and the photograph of yet another patient was exhibited who had survived thirteen operations for the relief of the condition. The instance I record also illustrates another curious experience which is generally agreed upon—namely, that an extensive operation may save the life of a patient when the osteomyelitis complicates an acute suppurative inflammation of the frontal sinus which hitherto has not been operated upon: whereas, when the frontal bone becomes infected after, and as a result of an operation on the frontal sinus, the issue is practically always a fatal one in spite of the most extensive operations for the removal of the infiltrated bone.

2. It may be asked why at the first operation, and seeing that the frontal bone diploë were infected, I did not proceed at once to a more extensive removal of the bone. My answer is that the disease had existed only for some ten days, and I hoped that by freely opening the frontal sinus and providing for subsequent drainage the diploë bordering on the sinus might recover, and even if they did not do so the infected area might become delimited in the course of a few weeks, and involve less traumatism in its

removal than if I had proceeded at once to an extensive operation. Furthermore, with such an acutely infective condition I was anxious not to expose more healthy tissue than the immediate necessities of the case demanded.

3. Opinions vary as to whether the complication is more likely to follow operation on an acute or chronic empyema of the sinus. In my own practice I have had three cases which terminated fatally, and have seen several others in consultation, but in all of them the complication has set in after operation on a chronic suppurative inflammation.

4. With regard to the method of exposing the frontal bone, I should not use the median forehead incision again because it leaves a noticeable scar. In a more recent case I laid bare the infected region by a transverse incision commencing in the middle line beyond the hair, and passing downwards and outwards to the temporal fossa, then directly forward to the outer angle of the eyebrow, where it joined the frontal sinus incision below the line of the eyebrow. The included portion of the scalp was then turned upwards and inwards towards the middle line. The small incision in the exposed portion of the temporal fossa healed by immediate union, and is no longer easy to detect.

FIG. 1.—Osteomyelitis of skull resulting from septic infection of the diploë after operation on the frontal sinus. The patient died after nine months of suffering, and after numerous operations for the removal of abscesses in different regions of the body. a, Sequestra; b, longitudinal sinus; c, left frontal sinus (anterior wall removed). This was the first recorded case in which the sequence of osteomyelitis as a complication of nasal sinus suppuration was detected (vide BRITISH MEDICAL JOURNAL, 1889). Surgeons interested in the subject are advised to read Dr. Dan McKenzie's monograph on the subject (*Journ. Laryngology*, vol. xxviii, 1913).

* The nature of the lesion can best be illustrated by reference to the illustration of a more extensive and fatal case.

5. When osteomyelitis complicates an operation on the frontal sinus it usually makes its appearance as a non-inflammatory oedema in the soft parts which cover the margin of the bony wound, and this sign is still more ominous if an area of oedema appears at some distance from the wound in the sinus. A coincident rise of temperature may be noted. If such a swelling be incised no pus escapes, but the wound does not heal and suppuration soon makes its appearance, while the oedema spreads still further.

The only treatment of any value in such case is to expose the frontal bone very freely and to remove its whole thickness involving a liberal area of healthy bone around the inflamed region. Delay and hesitation are unpardonable, while fomentations, incisions in the oedematous areas, or the administration of vaccines only betray the ignorance of the surgeon as to the grave condition of his patient.

6. As to the cause of the complication, my impression is that it is due to two details in faulty technique: (1) When the sinus is opened and the diploic spaces in the margin of the bony wound are exposed, infective material is introduced into them by curetting the walls of the sinus with a small sharp spoon. The diseased and pus-infected mucous membrane should be wiped away gently with small sterile swabs. (2) The lips of the wound in the soft parts should be left widely open and only the lightest packing placed in the sinus cavity. Since adopting these precautions I have experienced no anxiety in any of my cases.

It may not be out of place to state that opening an acute or chronic empyema of the frontal sinus by the intranasal method does not exclude the possibility of osteomyelitis of the frontal bone, for at least one case has already occurred, the details of which may be studied in the *Journal of Laryngology*, June, 1917, p. 186.

A NOTE ON THE ASSOCIATION OF HERPES ZOSTER WITH ARSENIC.

BY

HILDRED CARLILL, M.A., M.D. CANTAB., M.R.C.P.,
NEUROLOGIST TO THE ROYAL NAVAL HOSPITAL, HASLAR.

It is well known that arsenic administered in large quantity may have a harmful effect on the nervous system, both central and peripheral, and from time to time cases of herpes zoster have been recorded which have been ascribed to arsenic. Hutchinson was one of the first observers to point out this association.

Herpes zoster is looked upon commonly as being secondary to some change, either haemorrhage or inflammation, in the posterior root ganglia of the spinal nerves, but it has been recognized for a long time that the lesion is not confined to these ganglia. For instance, in some cases the cerebro-spinal fluid has been found to contain a well-marked lymphocytosis, pointing to involvement of the meninges, and in others the occurrence of Kernig's sign has suggested that the posterior roots have not escaped the inflammation.

Many cases of herpes zoster have been described which have been associated with, or followed by, a generalized vesicular eruption, and Dr. Parkes Weber¹ has recently summarized some of these. It has been suggested that herpes zoster is a modified and localized form of varicella, but the evidence of this is by no means conclusive. On many occasions the apparent connexion between these two diseases has been noted. There can be little doubt, however, that some of the cases were examples of a generalized shingles, but in others true herpes zoster appeared to have been produced from contact with a patient suffering from varicella, and vice versa.

The following case is of interest, as it relates both to the question of the association of arsenic with herpes zoster and also to the question of generalized herpes zoster:

A naval officer, aged 54, was seized during January, 1916, with an attack of multiple adenitis, together with paresis of the lower limbs and retention of urine. Except for the fact that he had spent twenty-three years in India there is nothing in his history which appears to have any bearing upon his illness.

He was a stout man of close on 15 st. in weight. On admission to Haslar on February 25th, 1916, he was found to

have almost complete paraplegia of the upper motor neurone type. The lymphatic glands in his cervical, pre-auricular, axillary, and inguinal regions were markedly enlarged and somewhat tender. There was no palpable enlargement of the spleen. The red cells were 4,500,000 and the white cells 3,000 per cubic millimetre. Of the latter, 50 per cent. were polymorphonuclears, and there were 2 per cent. of eosinophiles. The colour index was 0.77. His systolic blood pressure was 150 mm. of mercury. There were no visible haemorrhages. The Wassermann reaction of his serum was negative (Fildes). The cerebro-spinal fluid was not examined.

The connexion between the glandular enlargement and the paraplegia was not very evident, nor indeed was the nature of the adenitis. We were unable to obtain the consent of the patient to the removal of a gland. There was no evidence that the mediastinal glands were involved. Towards the end of March his general condition, other than that of the glands, had improved considerably. Treatment by liquor arsenicalis was commenced, and he continued with it until May 9th, 1916, when he went on convalescent leave.

On July 5th, 1916, he was readmitted, looking and feeling much better. He was able to walk quite well. The condition of the glands appeared to be about the same as when he was last seen. He told us that he had been taking the medicine throughout. On July 10th an eruption of herpes appeared on the right side of his abdomen. It assumed considerable dimensions, and covered roughly the area of skin corresponding to the eighth, ninth, and tenth dorsal segments of the cord. The eruption was not preceded by any pain but it was associated with pain when it was fully developed. By this date he had been taking 15 drops of Fowler's solution daily since March 23rd, a total of some 1,600 drops, or, roughly, 15 grains of arsenic. The eruption rapidly became generalized, vesicles appearing over the face, body, and limbs; the eyelids were considerably swollen. After a short time the eruption healed in the usual manner, and on July 28th the patient was discharged to his home. The condition of the glands was not materially altered. The temperature was normal throughout, except during the time when he was suffering from herpes.

Photograph taken to show enlargement of glands and healing herpes on July 26th, 1916. A few of the generalized vesicles can be seen.

The Croonian Lectures ON

ADAPTATION AND DISEASE.

DELIVERED AT THE ROYAL COLLEGE OF PHYSICIANS,
LONDON, JUNE 26TH, 1917.

By J. G. ADAMI, M.D., F.R.S.,
TEMPORARY LIEUT.-COLONEL C.A.M.C.

LECTURE IV.

THE PHYSICO-CHEMICAL BASIS OF IMMUNITY AND
EVOLUTION.

(Abstract.)

In the previous lectures it had been shown that the studies upon pathogenic bacteria and upon immunity proved conclusively the existence of direct adaptation of a definite order, both in the lowest and in the highest forms of life. To the academic biologist such a suggestion of a direct action of external agencies as a prime cause of variation is as shocking and improper as would be the suggestion of a risqué story to some dear, modest elderly maiden lady. And yet it is along these lines that medical research is surely leading us.

Believing that we are in the right, where is it that the biologists have gone wrong? It was suggested that the

biologists, from the morphological trend of their studies, have perforce conjured up separate individual particles or structures, each the bearer of an individual property or group of properties. Their conceptions have perforce been in the terms of specific atoms. In his Pangenesis hypothesis Charles Darwin evolved such a conception, and in his great sanity cast it aside. Weismann rioted in such, with his *ids*, *idants*, and determinants, all figments of the imagination. The same tendency is shown and carried forward in full vigour by the modern Mendelians. It is because he cannot picture in his mind an atom or structure suddenly making a first appearance in the germ cell, after the manner of Venus rising from the sea foam, that Professor Bateson finds it impossible to imagine the positive acquirement of new properties by the individual or the race. He found himself in the predicament of the late King George of glorious memory and muddled, who could not imagine how the apple got into the dumpling.

Suppose we start instead from known facts and known phenomena, and upon these endeavour to build up our idea of the nature of the germ cell and of the organic basis of heredity. First, as to the constitution of living matter—we know that whatever form of life we investigate, animal or plant, mammoth or microbe, whatever form we analyse, or whatever tissue, leaving out of account water and certain vehicular salts to which no specific vital functions can be attributed, just one order of highly complex compounds is common to and to be isolated from all, and these are the proteins. This universal presence in itself indicates that they are intimately associated with vital functions. When isolated chemically they are inert; in other words, living matter contains proteinogenous, rather than protein substances. A large portion of the lecture was taken up with a study of the chemistry of the proteins in relationship to metabolism; the huge size of the protein molecule, close to the limits of visibility under the highest power of the microscope; its great molecular weight; the impossibility of gaining identical analyses of two samples of the same protein, even if, like haemoglobin, crystallizable; the structure of these molecules; their dissociation into smaller complexes, the peptones; their further dissociation into amino acids; the synthesis of the polypeptides. The protein molecule may, therefore, be represented as a ring or chain of linked peptone molecules, each having its ring of glyco-cell nuclei with swinging side-chains. In the much simpler bodies with which the organic chemist is in the main concerned, bodies like the carbohydrates or the benzol derivatives, we know how the transfer of a given radicle from the *alpha* to the *delta* position, for example, upon a ring, may bring about a profound change in the chemical and physical properties of the compound. When two carbon atoms are united together there are, or may be, six free affinities, and when these are satisfied by six different univalent groups, twelve different isomeric arrangements are possible. What must be the possibilities in a protein like haemoglobin, with 700 and more carbon atoms in the complex? and haemoglobin is simple compared with the nucleo-proteins.

If the biophores, or molecules of living matter, be at least proteinogenous, obviously it is not necessary to demand a separate determinant, a separate molecule for each specific property; it is simpler to regard properties inherent in the biophores as an expression of the constitution of the same, of the mode of linkage of the various nuclei, their number and the nature of their side-chains. This conception is within the bounds of physical possibility; Weismann's *ids* and *idants* certainly are not.

Accepting this conception of the chemical constitution of the essential living matter as a working hypothesis, we know that in conjugation the one element of the germ cells contributed in approximately equal portions by both parents to the zygote, or fertilized ovum, is the nuclear chromatin, and as heritage of properties may come equally from either parent, in the nuclear chromatin must reside the main heritable and character-determining material. The conclusion is inevitable that the essential biophoric molecules are conveyed in the nuclear chromatin. The cell wall, or membrane, the cytoplasm and the nuclear membrane, are all conservative agents, tending to preserve the biophores from sudden change from without, but while conservative, this system is exposed to constant change, particularly in the more active tissue cells. The system is not inert, but is constantly reacting with the external

medium in which the cell finds itself. The semi-permeable cell membrane, while preventing the entrance of some substances, freely permits the entrance of others, whether directly or after a preliminary dissociation into smaller molecules by the action of extracellular enzymes. Once foodstuffs are taken into the cytoplasm they are, if necessary, broken down into yet simpler molecules by intracellular enzyme action. Foodstuffs are not utilized by the cell as such, but only after dissociation and disintegration, and then either by oxidation to supply energy or, on the other hand, to be built up in growth.

This matter of growth is wholly neglected by the biologists. They speak of inorganic bodies (crystals) growing by agglutination, organic bodies by intussusception. "Intussusception," "imbibition," "intercalation," and "interpenetration" are all inane terms; they cannot possibly explain how two molecules of living matter appear where there was but one before, two grains of wheat where but one was put into the ground. Growth is one of the great underlying phenomena of living matter, and zoologists and botanists have in a simple Topsy-like manner been satisfied that the phenomenon occurs—and have left it at that. Increase in the amount of living matter means multiplication of the molecules of living matter, and this multiplication can only take place after the manner of the growth of a crystal, by ions arranging themselves into radicles, and radicles arranging themselves in a particular order, until in orderly sequence the necessary radicles become built up, identical in arrangement with the pre-existing molecule, in association with which the group has become developed. This conception is materially aided by the recognition that crystallization does not of necessity demand the production of rigid rectilinear figures. Lehmann in 1904 first called attention to the existence of "fluid crystals"; in 1906 Adami and Aschoff pointed out that these fluid crystals are frequent in the animal organism. As D'Arcy Thompson remarks, "The phenomenon of liquid crystallization does not destroy the distinction between crystalline and colloid forms, but gives added unity and continuity to the whole series of phenomena."

The lecturer then passed rapidly in review certain conclusions which develop out of this conception of living matter. Weismann's doctrine of the continuity of the germ plasma was shown to be erroneous; it is not the germ plasma which is eternal, merely there is a potential continuity of molecular arrangement and constitution. The functional and vegetative activities of the organism and the cell were passed in review, along with the essential nature of metabolism and enzyme action, all these in order to emphasize that these matters of adaptation and evolution have to be approached from the aspect of function and the dynamics of living matter, rather than from the point of view of cell statics. "Function precedes structure," and the study of cell function must afford the key.

As regards the acquirement of the new power of digesting and utilizing a foreign protein, it is seen from what has been said that these proteins are complexes of amino-acids, and the number of the individual amino-acids is limited. Proteolytic enzymes, already in existence, whether intracellular or extracellular, do not attack the foreign protein as a whole, but must be regarded as dissociating certain everyday amino-acids from the complex. But doing this, to take the simplest case, the relative number of molecules of the different amino-acids presented to the cell may come to differ from the normal; or, again, the simpler complexes due to the breaking down of the foreign proteins may not be identical in constitution with those which the cell and its biophores had been accustomed to utilize in growth. In either case the constitution of the biophores may become altered as they are built up. Where enzyme-like bodies such as the toxins and phytotoxins become introduced into the cytoplasm, their toxic function must be regarded as due to their power of dissociating the living molecules, by detaching certain radicles. If the toxin molecules be not present in too great a number, time is given for the living molecules to attract and build up again the lost radicles, and by the law of habit, if this process be constantly repeated, particular radicles are now built up in excess of the needs of the cell, and undergoing discharge become the antitoxin bodies of the blood and body fluids.

That this conception of the mechanism of immunity and

progressive adaptation is substantially correct was, he urged, strongly supported by the long-continued and admirable studies of Professor Victor C. Vaughan of the University of Michigan, and the later work of Abderhalden of Berlin and his pupils. These observations and their significance were discussed in some detail.

Colonel Adami next attacked the prevalent conception of the Mendelians that the parental unit-properties remain segregated in the germ cells. In the zygote, the fertilized germ cell, and in all the tissue cells derived therefrom, it is inconceivable that two orders of biophores or active living molecules can exist floating in a common nuclear sap, undergoing growth, building up side-chains and radicles, discharging certain of these or undergoing dissociation from time to time, without the two reacting upon each other and without a certain amount of interchange, without the one having a greater affinity for side-chains elaborated by the other, and building these into its system. There must be this interaction, and at a slower rate, due to their more latent state, this same interchange must take place in the germ cells. Along these lines it is still possible to interpret the facts of Mendelism, and indeed interpret not a few phenomena which by the hypothesis of determinants fail to obtain explanation.

Briefly, each species must be regarded as having for its essential living matter a distinct organic compound—a compound as distinct as any inorganic salt, but differing from that simpler salt in that whereas the central ring or chain is to be regarded as having a relatively fixed constitution, the radicles composing that ring or chain are to be regarded as capable of attracting and then reproducing a series of side-chains which may vary in constitution, so that within the species there may be various strains, just as we may speak of various strains of crystalline haemoglobin obtained from different samples of human blood.

It is possible to replace an impossible hypothesis based upon supposititious, independent, and transposable determinants by one based upon our present knowledge of the composition and properties of the main and outstanding constituent of living matter—the proteins. To one who regards life, not from the morphological point of view, in terms of form, but from the physiological, in terms of function, who regards life as a moving equilibrium, who regards it as in essence “a state of persistent and incomplete recurrent satisfaction and dissatisfaction of certain proteinogenous molecules” and metabolism as the primary and basal characteristic of living matter—for such a one Professor Bateson's stumbling-block does not exist.

The Batesonian hypothesis of a backward evolution by the progressive removal of inhibitory factors, like the baseless fabric of a vision, fades into nothingness once it is confronted by the proof that direct positive acquisitions can be brought about experimentally. It enters into the limbo of the past as an example of the Spencerian tragedy—that of a deduction destroyed by a fact.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

X-RAY TREATMENT IN LICHEN PLANUS.

IN the following case the immediate relief and rapid disappearance of intense itching, the prompt subsidence of the eruption, and the restoration of healthy circulation in the hands under x-ray treatment, as evidenced by the freedom from cold hands, swollen fingers, chilblains, and frost bites during the past exceptionally severe winter, are worthy of notice.

The patient was a girl aged 12 years, of delicate constitution, subject to cold hands and swollen fingers even in the summer, and to very severe chilblains and frostbites in mild winter even. She was given galvanic and faradic Schnee baths on September 19th, 23rd, 27th, and 30th, October 7th and 20th last, with the view of improving the feeble circulation in the hands. On October 7th the patient complained of slight pain and smarting at the séance. On October 20th the pain and smarting were worse, and on careful examination a few scattered papules were noticed on the hands and more on the forearms. The swollen condition of the fingers and the cold feeling in the hands improved under galvanic and faradic treatment. By October 28th the eruption had extended to all the fingers of both the hands and more up the forearms, becoming confluent in most places. It was very itchy, and consisted of slightly elevated

violaceous papules of the size of pinheads, with flattened glistening top, slight central depression, and dry rough surface. There was a return of the swelling of the fingers. No more Schnee baths were given.

In spite of ointments and internal medicine there was a rapid extension of the eruption, and a decided aggravation of the itching and other symptoms. The itching was so troublesome as to interfere with proper sleep.

A mild stimulating dose of x rays was given on November 15th. This was followed by marked relief of the itching, which disappeared altogether in about a week. There was no further extension of the eruption, which looked darker and flatter. A second dose was given on November 22nd. The patient was now quite free from the troublesome itching, and there was a retrogression of the eruption. By December 4th, when a third treatment was given, the eruption had almost disappeared from the right hand and forearm, and only a little was left on the other side. The swelling of the fingers had also subsided. The last x-ray treatment was given on December 18th. Desquamation commenced soon after and continued till about December 31st. The remnants of the eruption and every trace of the complaint had altogether disappeared by that time.

Note.—The patient, it appears, had some spots on the forearms for a couple of months before the Schnee baths were given. Apparently the baths, instead of acting beneficially, aggravated the complaint.

M.R.C.S., L.R.C.P.Lond.

PREVENTION OF CEREBRO-SPINAL FEVER.

COLONEL PARKES's communication¹ with reference to this subject is most interesting and instructive, especially to any one connected with soldiers. Last winter somewhat the same procedure was carried out by me in the battalion of which I am medical officer. I used three ounces of formalin to the gallon of water in a “Killgerm” sprayer. I had no opportunity to have the sick with infective throats examined bacteriologically, but all sick with any “catarrhs” were sent each morning to a large room in a billet, and whilst this was being sprayed the men were kept in it for twenty minutes. We had not the success of the New Zealanders in eradicating the disease. Out of a battalion whose strength at that time averaged 2,500 men, three cases of cerebro-spinal fever developed in the season.

The same treatment has been used again this season. The sprayer is set going in a large room each morning, and all “catarrhal sick” are put there for twenty minutes. I have varied the solution, sometimes using formalin and at others “pacolol,” which is really Pearson's lysol. The latter is less irritating, and much preferred by the men. We have had so far one case of cerebro-spinal fever whose history is somewhat instructive. In the case of this patient there was no question of overcrowding. His room was on the sea front, containing 1,680 cubic feet, and there were four men in it.

Pte. N., after eleven weeks' service, was passed fit for draft leave, January 31st to February 5th, 1917. On February 8th he reported sick, with eighteen of the same company, with sore throats and the usual catarrhal symptoms. He had no fever. Was ordered “medicine and no duty” on this and the following day; and “medicine and light duty” on February 10th. From the 10th to the 15th he went on duty and was apparently perfectly well.

On February 15th, at sick parade (7 a.m.), he reported ill, with diarrhoea and sickness. He was ordered “medicine and no duty.” At 2 p.m. he again reported, as directed; his temperature was then 103°, and he was dazed and almost collapsed. He was sent to hospital, and next day cerebro-spinal fever was diagnosed.

As a means of attacking the nasopharynx the steam sprayer is very well worth trial. I intend to use the 1 per cent. sulphate of zinc solution to see if there is any virtue in this drug.

AMB. ATKINSON,

Lieutenant R.A.M.C.

¹ BRITISH MEDICAL JOURNAL, February 24th, 1917, p. 262.

ACCORDING to the *Med. Klin.*, medical practitioners in Vienna are experiencing increasing difficulties in getting to and from their patients, owing to the shortage of vehicles and motor power. There are only a few motor cars and cabs available, and their proprietors refuse all but short journeys. For several months the electric trams have enabled practitioners to carry on, but, owing to the shortage of coal, this service has had to be greatly restricted. It is therefore proposed that doctors with patients in distant parts of the town should communicate over the telephone with colleagues living in these parts and get them to attend to the distant patient.

Rebielus.

ADRENAL INSUFFICIENCY.

THE articles making up Dr. E. SERGENT'S study of adrenal insufficiency¹ have all been published previously; the earlier ones date back to the time when Addison's disease was practically the only recognized symptom complex in connexion with the adrenals. By his numerous contributions the author has helped to build up our present views as to the important part played by acute adrenal inadequacy in the fatal outcome of acute infections and intoxications.

The first step was to describe, in conjunction with L. Bernard, the syndrome of acute adrenal insufficiency, which includes cases previously regarded as examples of acute Addison's disease or sudden death in the course of Addison's disease. In such cases there may be outstanding lesions of the adrenals which have been completely latent until under the influence of some acute infection or intoxication acute inadequacy occurs. Observation of cases of acute adrenal inadequacy with meningeal symptoms of sudden onset and fatal termination led to Sergent's emphasis on the sign of the "white line," the reverse of the familiar *tache cérébrale* and due to reflex vasomotor spasm, as a diagnostic manifestation of adrenal inadequacy. Thus it is constant in Addison's disease and is a phenomenon of low blood pressure, with which it varies directly, being therefore present in enteric fever, diphtheria and other analogous conditions. The significance thus attached to "the white line" has aroused criticism, especially from Sergent's former collaborator, Bernard, who considered that its inconstancy and its intermittency even in the same patient deprived it of any diagnostic importance.

Allied to Addison's disease, which is due to chronic and extreme adrenal inadequacy, is the condition termed "Addisonism" by Boinet. This is seen in patients with pulmonary tuberculosis who in the course of the disease present symptoms indicating more or less functional disturbance of the adrenals, such as pigmentation, muscular weakness, and low blood pressure. Chronic adrenal inadequacy is considered also to play a part in neurasthenia, psychasthenia, chorea mollis, shock, especially after operations, and in some cases of the uncontrollable vomiting of pregnancy in which the adrenals are damaged by the toxæmia caused by the syncytial cells.

The numerous conditions ascribed to adrenal insufficiency—ascriptions, in some instances, open to criticism—lend interest to the concluding section on the therapeutic uses of adrenal preparations. In dealing with their form and method of administration Sergent expresses a preference for the fresh glands or their extract in chronic or acute cases in which asthenia is the predominant symptom, and states that adrenalin is satisfactory for cases in which a low blood pressure is prominent. The daily dose of the fresh glands should be $1\frac{1}{2}$ to 2 grams at first, rising later to 5 grams. The oral administration of twenty to thirty drops of 1 in 1,000 solution of adrenalin daily acts so quickly that hypodermic injection is not regarded as necessary.

This series of articles will be of special interest to those attracted by the history of the evolution of our present knowledge of adrenal inadequacy.

THE BIOCHEMICAL TREATMENT OF CONSUMPTION.

THE sanguine prophecies for the speedy annihilation of consumption as a national disease have not been fulfilled. The incidence of tuberculosis is still appalling and the death-rate shows no signs of further reduction. By comparison with the figures of two generations ago, there has undoubtedly been improvement in both respects, but it would appear to have come to a standstill. Hygienic methods and the avoidance of foul air have done much for individuals, but the disease is still rampant in communities where it is fostered by overcrowding and other evils.

From the purely curative point of view it has long been obvious that sanatorium life is only successful in a limited

number of cases, and that the disease progresses in spite of it. In other words, the unaided forces within the body, even under the most favourable conditions, are insufficient to cope with the ever-increasing inroads of the pathogenic organisms with which they have to contend. Hence it has come about that effort is more concentrated upon the problem of aiding these natural forces by methods which have been worked out through laboratory experiments.

The destruction of the microbes *in situ* by purely chemical methods would seem to be a hopeless task, but it is claimed for a few such drugs that a certain measure of success can be achieved. In a recent work by Dr. CROFTON of Dublin on *Pulmonary Tuberculosis*,² the use of iodoform introduced direct into the venous circulation is advocated as a means of local treatment, to be used as supplementary to specially prepared vaccines to increase opsonic power, and tuberculin to aid specific immunity. Recognizing that catarrhal processes play an important part in all pulmonary affections, he emphasizes the need for preliminary treatment by means of special vaccines prepared from catarrh-producing microbes, to be followed by the more direct attack upon the tubercle itself aided by the general antiseptic effect of the iodine and ether introduced into the vein. The train of reasoning by which he has arrived at this somewhat ideal method is given in detail, and the various risks and untoward effects to which it may give rise are not overlooked. The treatment, however, was only begun in 1913, and has had to be to a great extent suspended during the past three years. The results, given only in percentages, would appear to be encouraging, but details are wanting. Dr. Crofton's book presents the whole subject of the treatment of consumption in the most modern light, but it remains to be seen whether his scheme is justified by experience as time goes on.

NOTES ON BOOKS.

FOUR volumes of collected papers have reached us from the United States, but owing to the great restrictions on our space, detailed account of their contents cannot be undertaken. This brief notice will, however, serve as a finger-post to readers in this country. *The Transactions of the Thirty-eighth Annual Meeting of the American Laryngological Association*,³ held at Washington last summer, contains some twenty-five communications, mainly on the surgery of the upper air passages and accessory sinuses, with a number of clear illustrations. *The Surgical Clinics of Chicago*,⁴ of which we have received the first number, is a new bi-monthly publication intended to take the place of the *Clinics* of the late Dr. John B. Murphy. The contributors include many well-known surgeons, and the graphic and rather informal style of the reports gives the idea that they have been taken down at the bedside or in the clinical lecture theatre. The illustrations are very good. *The Medical and Surgical Reports of the Episcopal Hospital*,⁵ Volume III, consist largely of papers based on work done in the Episcopal Hospital in Philadelphia, and cover a wide variety of subjects. A number of the articles are reprints from American periodicals. *The First Annual Report of the State Department of Health of Massachusetts*⁶ contains Dr. A. J. McLaughlin's report as Commissioner of Health on the work of his department. Until the end of 1914 Massachusetts had a State Board of Health; this was abolished, and in its place was set up a State Department of Health organized on a far more effective basis, of which an account is given in this report. The Commissioner of Health is the administrative head of the department, performing all the executive duties formerly required by law of the State Board of Health. Thus one full-time official, "skilled in sanitary science and experienced in public health administration," is made responsible instead of an unpaid Board of seven members.

² *Pulmonary Tuberculosis: its Diagnosis, Prevention, and Treatment*. By W. M. Crofton, M.D., Visiting Physician Royal National Hospital for Consumption in Ireland. London: J. and A. Churchill, 1917. (Cr. 8vo, pp. 122; illustrated. 6s. net.)

³ *Transactions of the American Laryngological Association*. Vol. III. New York: Published by the Association. 1916. (Demy 8vo, pp. 525; illustrated.)

⁴ *Surgical Clinics of Chicago*. Vol. I, No. 1. Philadelphia and London: W. B. Saunders Co. 1917. (Demy 8vo, pp. 221; 83 figures. Published every two months; price per year, foreign, £2 2s.)

⁵ *The Medical and Surgical Reports of the Episcopal Hospital*. Vol. III. Philadelphia: Wm. J. Dornan. 1915. (Demy 8vo, pp. 356; 124 figures.)

⁶ *State Department of Health of Massachusetts*. Boston: Wright and Potter Printing Co. 1916. (Demy 8vo, pp. 330.)

¹ *Études cliniques sur l'insuffisance surrénale, 1895-1914*. By Émile Sergent, Médecin de l'Hôpital de la Charité. Paris: A. Maloine. 1914. (Post 8vo, pp. 493.)

MEDICINAL AND DIETETIC PREPARATIONS.

Halazone for the Sterilization of Water.

IN the BRITISH MEDICAL JOURNAL of May 26th, 1917, p. 682, Dr. H. D. Dakin and Major E. K. Dunham (U.S.A.) described the preparation of *p*-sulphondichloraminobenzoic acid and its value as a disinfectant for polluted water. They proposed the name "Halazone" for the substance and suggested that it should be put up in tablets, each containing four milligrams. This suggestion has now been carried out by Messrs. Burroughs, Wellcome, and Co., who have made a "tabloid halazone" containing 4 mg. of the disinfectant, the quantity stated by Dakin and Dunham to be sufficient to sterilize a litre or quart of reasonably heavily contaminated water; in the case of extreme contamination a second tablet may be necessary. The tabloids made by Messrs. Burroughs, Wellcome, and Co. dissolve gradually in about five or ten minutes, and the water should be allowed to stand for about forty minutes before use. Dakin and Dunham insist upon the importance of the tablets being stable. Messrs. Burroughs, Wellcome, and Co. state that their tabloids fulfil this condition, but upon that we are not able to express any opinion. The tablets must be kept in amber bottles and not exposed to sunlight. They are supplied to the medical profession in bottles of 100 at 8d. each.

EPSOM COLLEGE.

THE sixty-fourth annual general meeting of the governors of Epsom College was held at the offices of the College in Soho Square on June 29th. Sir HENRY MORRIS, the treasurer, presided. The annual report stated that there had been a slight increase in the number of scholars, and that the athletic and social life of the school had been maintained as far as possible in spite of the war. The Council tendered its thanks to the honorary local secretaries, to the British Medical Association, and to numerous friends of the College, who had collected contributions on behalf of the foundation during the year; and also to the editors of the BRITISH MEDICAL JOURNAL and the *Lancet* for numerous favours.

Sir HENRY MORRIS said that he thought on the whole a very satisfactory state of things was disclosed, both with regard to the school and to the benevolent fund. So far as the benevolent side of the work was concerned, while there had been a considerable diminution in annual subscriptions, yet the assistance which had been forthcoming from the honorary local secretaries, from the British Medical Association, and from other friends of the College, as well as the continued and increased exertions of the secretary and his staff, had enabled the Council to avoid, what would have been a very untoward circumstance, diminishing the number either of the pensioners or of the foundation scholars. Among contributions to the general funds of the College was one of £300 in debentures, given by Sir Ernest Goodhart and his brother, Dr. Gordon Goodhart, as a memorial to their deceased father, the late Sir James Goodhart, who was an old Epsomian. A matter to which the Council had set itself was the establishment of an endowment fund with the object of assisting foundation scholars—or others who might come to be in necessitous circumstances after being entered at the College, and were the sons of medical men—on leaving the school. Since the report of last year 130 more boys of the College had joined the services, bringing the total serving to between 600 and 700; 41 had been killed, 4 had died in hospital, 53 had been wounded, 2 were missing, 3 were prisoners, while 18 had been mentioned in dispatches, 4 had received the D.S.O., and 13 the Military Cross.

After the statement had been adopted, Dr. WALTER RIGDEN proposed, and Major CHARLESWORTH seconded, that the following be re-elected members of the Council for a further period of three years: Sir John F. H. Broadbent, Sir Frederick Needham, Sir Frederick Taylor, Mr. T. Hollis Walker, K.C., and Dr. W. Essex Wynter; and that Sir Ernest Goodhart, Mr. E. Climson Greenwood, Mr. Purnell Purnell, Captain Harold Spitta, and Dr. H. Campbell Thomson be elected to the Council to fill vacancies. This was agreed to.

Sir JAMES REID, in proposing a vote of thanks to Sir Henry Morris, said that it was hardly possible to think of Epsom College without at the same time thinking of its Treasurer.

HEALTH OF MUNITION WORKERS.

THE object of all industrial organization is to ensure a maximum output—that is, the highest output of which each machine and each worker is capable, but without detriment to the well-being, mental and physical, of the worker.

Theoretically it might be supposed, and has been assumed, that self-interest would be a stimulus to both employer and employee effective to ensure this result. Experience has shown that this was not always, or, indeed, usually, the case, and there had grown up a vicious system under which the two parties in an industry—the employer and employee—looked the one upon the other, if not as open enemies, at least as classes having opposed interests. Hence arose a state of things in which the employer's effort to cut the wages of the employed in the hope of cheapening production was met by a systematic check on output, which had the effect of slowing the rate of production and increasing its cost.

Under the pressure of a great war which made it essential to the existence of the nation that the output of munitions of war, of clothing, food, transport, and all the thousand and one things that the Admiralty, the Ministry of Munitions, and the War Trade Department demanded for the fighting forces should be speeded up, the majority of the trade unions agreed to the suspension for the duration of the war of regulations, rules, customs, and usages to which they attached great importance. Mr. Lloyd George, the first Minister of Munitions, gave an unconditional pledge that after the war the working conditions should be reinstated on the basis of what they were before the war. It is, however, inconceivable that either party will wish to go back to the conditions previously existing. Representatives of employers' associations and trade unions sitting together in a subcommittee of the Reconstruction Committee have recently (June, 1917) reported that—

In the interests of the community it is vital that after the war the co-operation of all classes established during the war should continue, and more especially with regard to the relations between employers and employed. For securing improvement in the latter, it is essential that any proposals put forward should offer to workpeople the means of attaining improved conditions of employment and a higher standard of comfort generally, and involve the enlistment of their active and continuous co-operation in the promotion of industry.

The Government has approved the general principles of a scheme for the establishment of a system of national councils working with district councils and works' committees, on all of which employers and workers would be represented, to secure better utilization of practical knowledge, a greater share and responsibility for workers in determining conditions under which work is carried on, including questions of wages and piecework payment, to utilize industrial research and inventions, and to encourage co-operation in carrying new ideas into effect.

MINISTRY OF MUNITIONS.

The demands for munitions and other supplies for the navy and army have increased rapidly to enormous proportions far beyond the capacity of arsenals and munition works existing in time of peace. When a Ministry of Munitions was constituted in May-June, 1915, it stimulated production by encouraging the conversion of factories, previously used for various trades, to the manufacture of shells and other munitions, and the establishment of new works. In his statement to the House of Commons on June 28th, 1917, the present Minister of Munitions, Dr. Christopher Addison, said the Ministry was now responsible for the employment of two million persons.

The success of the appeal of the Ministry of Munitions to men and women of all classes to take their share in increasing the production of munitions of war in the immense proportion necessary involved shifting workers, and often their families, from one area to another, the conversion of factories designed for one purpose to another, the improvisation of many others, and it raised many problems, and of these the most difficult were those concerning the health of the workers, including their housing, transport, the regulation of their hours of work, their feeding, and the general construction and administration of the factories themselves.

HEALTH OF MUNITION WORKERS COMMITTEE.

The medical side of the Factory Department of the Home Office developed for the administration of the Factories Acts, which may be said to date from 1833, though an Act dealing with allied questions was passed as early as 1819, had acquired a great deal of information as to the means of safeguarding workers from the diseases and accidents to which they were specially liable. But it was early understood by the first Minister of Munitions, Mr. Lloyd George, and his lieutenant, Dr. Christopher Addison, that the immense increase in the numbers engaged in a special class of work demanded an intensive study. They accordingly appointed a Health of Munition Workers Committee, under the chairmanship of Sir George Newman, Medical Officer to the Board of Education, comprising scientific medical men drawn from the National Medical Research Committee and the Factory Department of the Home Office, as well as representatives of employers of labour, and of women workers. It has taken evidence from employers and workers; it has visited factories and workshops; and it has set going special studies on fatigue, on the ventilation of factories, on the dietary of workers; on systems of wages as incentive to work, on the relative efficiency of night and day work, and a variety of other subjects. For these inquiries the services have been enlisted of physiologists such as Dr. H. M. Vernon and Professors Leonard Hill and Benjamin Moore; of medical officers such as Captain T. H. Agnew, R.A.M.C.; of selected women medical officers, of women inspectors of factories, of economists (Professor T. Loveday and Mr. Sargent Florence), and of a medical statistician, Captain M. Greenwood.

SUNDAY LABOUR.

In the first crisis created by the war work was carried on by night and day shifts and without intermission on Sundays. When it was realized that the war would be protracted, and on an ever-increasing scale of magnitude, it became obvious that the initial sprint could not be kept up in a long race, and that disastrous results might occur if provision for rest were not made.

The evidence received by the Committee led it to express a strong opinion that if the maximum output is to be secured and maintained for any length of time, a weekly period of rest must be allowed. Except for quite short periods, continuous work is an economical mistake, for output is not increased.

INDUSTRIAL FATIGUE.

The performance of work depends on the activities of (1) the complex nervous mechanisms of the brain and spinal cord which initiate and distribute impulses to action; (2) the nerves which conduct the impulses to muscles; (3) the muscles themselves. Fatigue is not to be compared with the running down of a clock weight, but with the clogging of the wheels by dirt. During rest the chemical products of activity are removed by the blood, and the active material restored. There is a definite relation between the degree of any given activity and the time necessary for the completion of the subsequent restorative process. Although, in the tired man, the symptoms of fatigue are referred to the muscles, which ache or give under him, yet the problems of industrial fatigue are primarily, and almost wholly, problems of fatigue in the nervous system and of its direct and indirect effects. The nervous system displays a wide adaptability in response to training and use. It is the problem of scientific management to discover, in the interests of output and of the maintenance of the health of the workers, what are the maximal efficiency and rhythms for the various faculties of the human machine. If the pace of machinery imposes too fast a rhythm upon the worker the result will be accumulated fatigue and diminished output. Practically the whole of the mechanical energy and heat yielded by the body during work comes from the chemical energy stored in the muscles. In proportion as this store is called upon it must be made good by supplies from the blood and ultimately from the food; the relation of good feeding to capacity for strenuous work is direct. Hence the enormous value of proper canteen arrangements and adequate wages.

The signs and symptoms of fatigue depend upon the nature of the particular work done. Its onset is insidious. A man's capacity for work may diminish from this cause

without obvious sign and without his knowing it himself. His time is then spent uneconomically, and for scientific factory management this point must be determined, since the results of overstrain not only reduce capacity at the moment, but do damage of a permanent kind, affecting capacity for periods far beyond the next normal period of rest. As the accumulated results of fatigue are damaging to general health, they will be reflected in the sickness returns and in the returns of lost time. It is, however, obvious that, without complete analysis of other variables, sickness returns will be only an indirect guide in the study of fatigue as such.

The most direct test of fatigue is afforded by the measurement of output in work under ordinary conditions and by methods which do not allow the workers to know when the tests are being made. The results of work expressed in output must be corrected by allowance for all variable factors such as changes in supply of power and of raw material. The output must be estimated for successive short periods (for example, each hour) of the day's work, so that the phenomena of "beginning-spurt" and "end-spurt," and other variations complicating the course of fatigue as such, may be traced and taken into account. Isolated tests of output taken sporadically will be meaningless. The records must also extend over longer periods to show the onset of fatigue over the whole day and over the whole week, and under particular seasonal or other conditions, in order to detect and measure the results of accumulating fatigue. In many factory processes it is easily possible to measure the output of particular individuals, and surprising variations of individual output, independent of personal willingness and industry, and generally quite unsuspected by the workers and their supervisors before the test, have been found. Information so gained is valuable in two respects. Good individual output is often the result of escape from fatigue by conscious or unconscious adoption of particular habits of manipulation or of rhythm. Its discovery allows the propagation of good method among the other workers. In the second place, these tests of individual capacity (or its loss by fatigue) give an opportunity for a rearrangement of workers and their assignment to particular processes. Astonishing results, bringing advantage both to employers and employed, have been gained by the careful selection of individuals for particular tasks, based, not upon the impressions of foremen, but upon the results of experiment.

In so far as hours of work in excess of those suitable for maximal efficiency have been imposed upon the workers a tradition of slowed labour has arisen, probably in large part automatically, as a kind of physiological self-protection.

In the present time of crisis patriotic incentive has done much to abolish customary reduction of effort among munition workers, but a special and strenuous voluntary effort in labour, if it be maintained under a badly arranged time-table of work and rest, does not necessarily bring increased output over a long period, however praiseworthy the intention of the effort may be.

In war time the workers may be willing, as they have shown in so many directions, to forego comfort and to work nearer the margin of accumulating fatigue than in time of peace, but the country cannot afford the extravagance of paying for work done during incapacity from fatigue just because so many hours are spent upon it, or the further extravagance of urging armies of workmen towards relative incapacity by neglect of physiological law.

HOURS OF WORK.

Great conflict of opinion was found to exist as to the number of hours that can be worked profitably by adult males. At the one extreme were the advocates of forty-eight hours a week, who held that all overtime beyond that was bad, and doubted whether even when worked to meet urgent demands the output of the factory were increased. At the other extreme were those who defended fifteen hours' work a day (6 a.m. to 9 p.m.), which was worked in peace time to meet temporary trade pressure.

After full consideration of the evidence of witnesses and the results of physiological investigation, the Committee came to the following conclusions:

1. The average weekly hours of war workers, exclusive of meal times, should not exceed sixty-five to sixty-seven a week, including overtime. Hours in excess of sixty-five

should be worked only for short periods to meet sudden and unexpected circumstances, and a rather lower limit for work requiring close individual attention is desirable.

2. The overtime should be limited to three or four days in the week, preferably not consecutive.

3. If overtime is worked, there should be no Sunday work.

4. Every effort should be made not to work boys under 16 for more than sixty hours a week, and where overtime is allowed substantial relief should be insisted upon at the week ends, so as to permit outdoor recreation.

5. The hours of work for women and girls should be even more closely safeguarded than for men and boys, and continuous work in excess of the normal legal limit of sixty hours a week discontinued.

Shifts.

The consideration that it is uneconomical to allow machinery to stand still is met better by the system of working in shifts than by overtime, whether the workers be men, women, or young persons; the two most common systems are a double shift, day and night, or three shifts, each of eight hours. The great advantages of regular shifts are that they involve less strain on foremen and workers, enable the machines to be used for the whole twenty-four hours, and produce a better and more uniform output. Difficulties of shortage of supervision and of housing and transit have interfered with the establishment of the system of eight-hour shifts for male workers, but not for women to the same extent. Girls under 18 should not be employed on night shifts, but where, owing to shortage of labour, this must be allowed, it should be restricted to girls over 16 years of age carefully selected for the work.

NIGHT WORK.

The imperative necessity of war has revived, after almost a century of disuse, the night employment of women in factories. Prohibited for the textile trades by the factory legislation of 1844, it disappeared gradually until it was banished by international agreement from the twelve European countries which signed the convention at Berne in 1906. The reports to the International Conference showed that deterioration in health was caused by the difficulty of securing sufficient rest by day, that the work done by night was inferior to that done by day, and that disturbance of home life had injurious effects upon the children also. If women are allowed to do night work adequate pauses for rest and meals are indispensable. The temperature of the human body exhibits a distinct rhythm during the twenty-four hours, with a maximum between 4 p.m. and 8 p.m. and a minimum between 2 a.m. and 6 a.m. The natural explanation of the rhythm is that it reflects the diurnal variations of bodily combustion, in particular that going on in the muscles. There is, however, no inherent reason why the accustomed routine of work and rest should not be reversed, for on travelling round the globe the reversal takes place, the temperature cycle conforming to local time. Against replacing day by night work is the influence of sunlight on health, but this influence is far less in factory and indoor than in outdoor workers. The average life of those who survive the age of 15 years is 67 in purely agricultural and 50 in purely manufacturing districts. The deprivation of the stimulating, health-giving effects of sun and wind must have a large share in shortening the life of the factory worker.

Inquiry has shown that night work has proved less exhausting than had been feared (except in the case of married women with children). A fair proportion of girls preferred it to the day shift, partly because of the higher wages earned, and partly because they gained a little time for recreation or shopping; most seemed able to sleep sufficiently well by day. The output of munition factories where the shifts change weekly from day to night in fact seems to be almost as well maintained by night as by day. Any considerable difference—exceeding, for instance, 10 per cent. or 12 per cent.—points to the existence of some defect in organization, and should be regarded as a danger signal calling for special inquiry as to the conditions of work.

The permanent employment of women in night shifts is inferior, whether measured in terms of hourly output or of lost time and inconstancy of employment. This inferiority, although not sufficient to make it imperative to prohibit

the system in the case of old-established factories, is of an extent to make it undesirable to adopt continuous night shifts in any shops not at present using it or not yet opened. This inferiority may ultimately be referred to a failure to secure proper rest and sleep in the daytime. Women on permanent night work may be relied on to perform domestic duties which, when they work alternately in the two shifts, is impracticable; and this extra domestic strain may account for the inferior results of their industrial activities.

LOSS OF WORKING TIME.

Professor T. Loveday has made a special study for the Committee of the chief causes of "lost time." Some are found to be in the main unavoidable under present conditions, such as the necessity of employing persons of inferior physique or irregular habits, lack of housing accommodation, lack of transport facilities, bad weather and dark streets, lack of material coming from outside, domestic duties in the case of married women, sickness, and accident. Others, in the main avoidable, are alcoholism, indifference, discontent with conditions of work, the early morning "quarter," overtime work, and faulty factory organization.

Holidays may untune the worker just as the nerve-racked soldier may be untuned by the over-sympathy of relations. Over-indulgence in food, drink, and sexual relations may contribute to this untuning. The regularity with which a greater number of quarters of days are lost on certain days indicates deliberate choice of these days; the preference for "sleeping in" on Monday, even when there has been no Sunday shift, disproves any direct connexion between overtime and much of the loss of early hours. If definite fatigue were the main motive the tendency would be, among men not engaged in work on Sunday, for most absences to occur in the second part of the week. Another negative argument is the heavy loss of quarters on the day after a general holiday. The true motive here, as on Mondays, is the drag of the flesh against beginning the same old grind again.

The important conclusion is reached that the early hours suitable for agriculture are an anachronism for factory hands. Work before breakfast yields an inferior output, lowers health, and leads to a great loss of time owing to the shortness of the first spell. In certain kinds of work the early quarter has been abolished with advantage. Absences of workmen, especially when unexpected, entail a certain amount of disorganization, and therefore (quite apart from questions of fatigue) so far as early hours or overtime cause loss of normal time, cost is increased and efficiency lowered.

JUVENILE EMPLOYMENT.

The problems of juvenile employment first became the subject of public discussion and legislative enactment more than a century ago. For a long time the English Factory Acts concerned only textile trades, but in 1867 they were extended to other industries. At the present time, when the war is destroying so much of the country's best manhood, it is necessary to guard not only against immediate breakdown, but also against the imposition of strains which may stunt future growth and development. Long hours of work by day or by night, often coupled with unsatisfactory conditions of housing and transit, late hours and lack of parental care, the monotonous toil and absence of opportunity for healthy recreation, make the dangers grave and immediate.

Under the Factory and Workshops Act, 1901, boys and girls under 18, and legally exempt from school, may be employed for twelve hours (ten and a half exclusive of meals) a day, and eight (seven and a half) on Saturdays—a maximum of sixty-two and a half hours weekly. Sunday work, overtime, and night work, subject to some exceptions, are forbidden. These regulations have been relaxed under the stress of the present emergency, and sixty-seven hours and even more—up to fourteen and even fifteen hours daily—have been worked; night work has been common, and Sunday work allowed, though latterly largely discontinued. Boys under 16 are probably more delicate than girls, and eight hours of sleep are essential, nine hours much better. Many get only six or seven!

In addition to the usual evidences of fatigue, muscular pains, aching feet, restlessness, sleepiness, and tired feeling, overworked boys have a vacant expression and a dry skin

with a rash. In a factory where conditions were bad the boys were spiritless, dull, and weary, while boys doing more than sixty hours' work a week in a factory where the conditions were good, whose homes were not in confined courts, and who had opportunities for open-air recreation, presented a striking contrast.

Welfare Supervision.

Bad time-keeping by boys may be the outcome of genuine fatigue, illness, home troubles, discontent, and lack of discipline. Boy visitors are being appointed at all the larger munition works to get at the true causes. When boys first go to a factory they find all the conditions strange, and one of the duties of a boy visitor is to look after the new boy during this period, and afterwards keep a record of his progress. The boy visitor would be entitled, after inquiry, to represent complaints to the proper authorities, to encourage recreation and sports among the boys in their spare hours, and generally to supervise their food and health. The plans for recreation include a playground, a boys' club, and a standing country camp for short rest periods during the summer. In some factories the new boys work together under special supervision, or in a gallery containing types of machines where they can be instructed in their use. While the high wages now earned by boys are beneficial by bringing good food and clothing within the reach of all, they may encourage thriftlessness, gambling, and extravagance. To encourage thrift patriotism is appealed to, and very simple systems for the receipt of savings established. It is believed that the records of the boys' careers will be of permanent value in throwing light on the many difficult problems arising out of the effect of occupation in youth upon the health.

KINDS OF WORK DONE BY WOMEN.

A special inquiry was made into the kinds of work done by women. The tool-setter's is a skilled art. It consists in making the automatic machines run smoothly, removing the tools for grinding and replacing them as expeditiously as possible. Trained tool-setters, who were limited in number, each now has a gang of learners under him. Very little skill is required from the automatic machine minder, but dexterity is necessary. The human element tells in the feeding of the machines. It must be continuous, and the materials fed must be put into the machine the right way on, for great delay will occur if the very delicately constituted machines are thrown out of gear. Lathe work requires slightly more concentration. Power and hand press work require considerable concentration, and the risk of accident is always present; in the hand press muscular action enters into account as well as mental strain. Examining and gauging are simple operations, but demand thought and attention, and require a quickened intelligence.

Munition factory work, though often monotonous and tedious, is not, as a rule, particularly exacting; the workers are not putting forth their whole energy all the time.

Protection of their Health.

The munition workers of to-day include women who were dressmakers, laundry workers, textile workers, domestic servants, clerks, shop assistants, university and art students—women and girls of every social grade who often had no previous wage-earning experience. They include also, in large numbers, wives and widows of soldiers, and many other married women who had given up industrial work and many who had never entered it. Conditions of work are accepted without question and without complaint which, immediately detrimental to output, would, if continued, be ultimately disastrous to health. It is for the nation to safeguard the devotion of these workers, and it may be that in the entanglement of problems new and old the coming of the new and their imperative claim for solution will help the solving of the old. The well-being of young girls fresh from school, of the prospective mother, and of the mother during the first months of her infant's life, more than ever call for sympathetic recognition. If proper care and forethought are exercised there seems no reason why women and girls, if suitably selected and supervised, should not carry out many operations, hitherto considered fit only for

men, without permanent detriment to their future health. A medical inquiry into the health of women workers showed that out of 1,326 examined 763 were healthy, 451 suffered from slight fatigue, and 112 from marked fatigue. The ailments most frequent were indigestion, constipation, headache, anaemia, and muscular pains. In one factory, nearly all the workers, especially the younger ones, took salts two or three times a week to obviate the effect of sedentary occupation and lack of open-air exercise; dental treatment appreciably lessened the amount of headache. Anaemia was particularly common where canteen and transit arrangements were defective. Disorders of menstruation under the conditions of employment were less marked than anticipated.

The general impression was that home duties and worries on the top of long shifts and night work formed too heavy a burden for the average married woman. A day began, owing to difficulties of transit, at 4 or even 3.30 a.m. for work at 6 a.m., followed by fourteen hours in the factory, and another two or two and a half hours on the journey back, might end at 10 or 10.30 p.m. in a home or lodging where the prevailing degree of overcrowding precluded comfortable rest. In one instance inquiry showed that of seventy-five women employed from 6 a.m. to 8 p.m. most lived within a mile or a mile and a half of the factory, but that none of them got more than seven and a half hours' sleep, and many less than seven hours. The majority rose before 5 a.m.; of these workers nineteen were over 21 years, but many between 16 and 18. If workers live near the factories they are not only spared the fatigue entailed by a journey in a crowded train or tram before and after work, but are able to take many meals at home and to have increased time for exercise and recreation, with a consequent distinctly good effect on their health. The fatigue of standing in a crowded car after a struggle to gain admission adds considerably to the severity of the day's work, and many of the girls complained of muscular pains in the feet and back.

The provision of seats where the work allows it, and for rest, is important. At one factory muscular pains were observed in 26 per cent. of the workers; seats were provided, and six months later the complaints of fatigue and headache had markedly diminished. Suitable seats of the deck-chair type can be made by fixing two strong horizontal rails, one 12 inches from the ground and the other 30 inches in front of it and 36 inches from the ground. Between the rails are fastened a series of strips of strong material 54 inches long and 18 inches wide.

Pauses for rest well distributed and adapted in length to the needs of the workers are of the highest value. The Factory Acts permit in textile factories a maximum of four and a half hours of unbroken work, in non-textile, five. Many managers think four hours a better limit, and a ten-minute interval within this period has been found to give excellent results. Factories ought to be planned in garden cities so that workers can go out into playgrounds for an interval of games and exercise whenever the weather allows it. The hygiene of the school in relation to work and play intervals should be extended to the factory. The vast size of modern workshops militates against this, for it takes too long to empty and fill them; the ideal, therefore, is to establish small shops each with its playground.

(To be continued.)

THE *Annals of Medical History* is a new quarterly periodical, the first number of which appeared in April. The four issues—Spring, Summer, Autumn, Winter—will make an annual volume of 500 to 600 pages. The new publication will contain original contributions, illustrated when necessary, on subjects connected with the history of medicine, with occasional reprints of epoch-making monographs. It is hoped in time to add special departments, such as abstracts, reviews, bibliographies, incunabula, notes and queries, and so forth. The Editor-in-chief is Dr. Francis R. Packard, of Philadelphia, and the publisher is Paul B. Hoeber, 67-69, East 59th Street, New York. Among the contents of the first number are papers by Dr. and Mrs. Singer on Girolamo Fracastoro, with special reference to his theory of infection; on the Greek Cult of the Dead and the Chthonian deities in ancient medicine by Dr. Garrison; on Voltaire's relation to medicine by Dr. Pearce Bailey; and on Hebrew prayers for the sick by Dr. C. D. Spivak of Denver.

British Medical Journal.

SATURDAY, JULY 7TH, 1917.

INDIA AND MESOPOTAMIA.

VISCOUNT HARDINGE'S speech in defence of his administration in India (p. 21) may have the effect of steadying public opinion by showing the number and magnitude of the problems with which the Government of India was faced immediately after the outbreak of war. It provided an army corps for France and Egypt, it furnished two expeditions to East Africa, and it undertook the Mesopotamia campaign. At the same time, it had to face serious attacks by the tribes on the North-West frontier more numerous and determined than had been experienced since 1897. It had also to keep a very watchful eye upon unrest in India, especially in the Punjab in the spring of 1915, and at the end of that year had to make extensive preparations to foil the German conspiracy to organize rebellion in Bengal and elsewhere. Lord Hardinge said that within three months of the outbreak of war the supply of hospital ships and of permanent hospital staff had been exhausted, and that it was only by great effort that many more ambulances, hospitals, and medical personnel were dispatched from India to the various theatres of war during 1915. He attributed the principal share of the breakdown of the medical service on the Tigris to the absence of sufficient river transport, though it was only, he said, in June and July, 1915, that the pressure first showed itself, and it was not until December that the facts as to the sufferings endured by the wounded began to trickle down from Mesopotamia to Bombay and Delhi.

This, in brief outline, is Lord Hardinge's apologia, and every point in it seems to apply with equal or greater force to the position of the Director of Medical Services in India. Surgeon-General Sir William Babbie took up the duties of that office in March, 1914. In the middle of February, 1915, he was detached to Egypt in connexion with war problems which had arisen there; he returned to India in March, 1915, and was finally withdrawn from India in June of that year because the need of his ability was experienced elsewhere in connexion with the war. The Parliamentary Commission recognizes that he showed promptitude and firmness in pressing war provisions on the Indian Government necessary for the overseas expeditions generally, and that on the outbreak of war he urged the formation of a fleet of ocean hospital ships, the construction of hospital trains, and the expansion of the Army Bearer Corps, a reform long overdue. The complaint of the Commission against Sir William Babbie is founded upon the belief that, as in other phases of the expedition, Mesopotamia was, in medical matters also, regarded as a "small side-show." It seems abundantly clear that it was so regarded by the Government of India, and not without good reason at the beginning. To quote Lord Hardinge with regard to river transport, this "could only have been met by preparation far in advance, which the gradual development of policy in Mesopotamia did not permit."

The report of the Commission is a voluminous document, very full of detail, and only a very close study with careful comparison of dates can enable a sound judgement to be reached, but it seems very clear

that even the Governor-General's Council was not made aware of the gradual development of policy. "Gradual development" is, perhaps, a rather euphuistic expression when it is made to include the hesitation and vacillation of the Home and Indian Governments and their military advisers with regard to the advance on Baghdad. Sir William Babbie told the Parliamentary Commission that he was not made aware of any intention of an extensive campaign up the rivers, that his preparations were made for a campaign limited to the conquest and retention of Basra and the oil fields, and that "if there had been a hint of Baghdad the arrangements would have had to be absolutely put into the melting-pot." He admitted that he knew from hearsay that both Amara and Nasariyeh were necessary for the defence of Basra and the oil fields, but hearsay is not enough for a responsible officer to act upon, and does not give him firm enough ground for making an appeal to a parsimonious finance department to disburse large sums of money which the Finance Minister desired to retain in order to make a flourishing financial statement showing that "our chief economy occurs under the military services."

With regard to equipment and personnel also, the same baleful influence has long been at work in India. Years ago a strong committee of medical officers recommended the introduction of the station hospital system with proper dieting and hospital clothing and bedding. It started, however, under the ban that anything it recommended was not to cost more money, but should, if possible, show a saving. Subject to this it made a recommendation, among others, for the introduction of the station hospital system, but nothing was done. The position with regard to the supply of instruments, dressings, etc., to British hospitals in India was practically the same, and the same thing happened in the case of medical supplies in the field, although by the persistence of the Director of Medical Services in India improvements in the equipment and the arrangements of the hospitals were approved and the establishment of station hospitals sanctioned, but afterwards cancelled. Sir Bruce Seton, who for thirteen years held appointments in the head quarters of the Government Secretariat in India, in a letter to the *Times*, in which he gives some of these particulars, says "no man could have done more than Sir William Babbie and his predecessor [Sir Alfred Sloggett] to avoid the very disasters which they foresaw, and no man could have supported them more heartily than the present Director-General I.M.S." (Sir Pardey Lukis).

We do not accept the conclusions of the Parliamentary Commission in the supplementary part of its report (Part X, par. 111), that the medical defects disclosed in Mesopotamia were not due to the shortage of river transport, that the sufferings of the sick and wounded were not, or need not have been, materially affected by the shortage of river steamers, and that such shortage did not prevent sufficient doctors and assistant surgeons being sent to the expedition up to the end of 1915, or prevent it from being supplied with sufficient hospitals. These opinions are in direct conflict with innumerable other passages in the report, and clash with its whole tenor. We unhesitatingly accept the conclusion of the Vincent-Bingley Commission that the fundamental defect was the shortage of river transport, which reacted on the medical organization both directly and indirectly. Its direct effects were not only to prevent a permanent allotment of river steamers to the medical services for use as hospitals and frequently

to retard the dispatch of medical units and stores to the front, but also on many occasions to force the military authorities to curtail the equipment and personnel of medical units in the field to a dangerous extent. Its indirect effects, the Vincent-Bingley Commission found, had been equally important, since it delayed the completion of hospital buildings, impeded provision of comforts for the sick, and affected the health of the troops, as it was the cause of incomplete rations being supplied to them. Moreover, that Commission held that if river transport had been more plentiful, better arrangements would have been made for supplying the troops with pure drinking water. The considered opinion of Lord Hardinge is that "it was principally due to the absence of sufficient river transport that the medical service on the Tigris broke down."

We are not interested to defend any medical officer who did not rise to the occasion, but we feel that the Parliamentary Commission has failed in its duty and deserves censure for ignoring the personal responsibility of the men who have for many years used their positions in the military finance branch and finance department of the Government of India to block every military medical reform.

ADAPTATION AND DISEASE.

AMONG the results of the special demands of the war on the medical profession there must be recognized a practical cessation of ordinary research work. For, owing to the shortage of the profession and the vast increase of routine laboratory investigations, there is little time for research into problems other than those of military importance. This is borne out by the recent Croonian lectures before the Royal Society and the Royal College of Physicians, which, as it happens, were both given by Fellows of the Royal Society (of which Croone was an original Fellow) hailing from Cambridge, the founder's Alma Mater. The lecturers, who are whole-time scientific workers and in peaceful circumstances might have been free to pursue fresh lines of experiment, in both instances developed as their themes the outcome of activities during fifteen or more years before the war. Colonel Adami's subject for the four lectures before the Royal College of Physicians was "Adaptation and Disease," a frontier subject between medicine and the ancillary science of biology, two such jealous mistresses that few indeed are qualified to speak with authority for both. From his work and association at Cambridge with biologists in the Eighties, and his pathological chair during the last twenty-five years at Montreal, Professor Adami is exceptionally fitted to attack this thorny problem and to dictate just terms between the rival territories of the normal and morbid biology, the champions of which, it must be admitted, often treat each other with a silence not entirely born of sympathy and respect. That he does so fearlessly and with some vigour is the outcome of loyalty to the medical profession and of pious regard for his physiological teacher and friend, the late W. H. Gaskell, whose great work on the origin of the Vertebrata met with such a chilly reception. Since 1892 Professor Adami has written on subjects allied to the present, such as the variability of bacteria, the inheritance of acquired conditions in man, a trenchant criticism of Weismann's theory (1901), adaptation and tuberculosis (1905), and heredity (Osler and McCrae's *System of Medicine*, 1907); and the time for such discussion is more than ripe, especially as Crile in various

publications, and most recently in *Man—an Adaptive Mechanism* (1916), has dealt with it on rather different lines.

The problem of evolution turns on the cause or causes of variation, whether, as most academic biologists maintain, variation is intrinsic and due to inherent tendencies in living matter, or whether it is the result of extrinsic influences—in other and more formal words, a direct adaptation in response to a specific alteration in the environment. Professor Adami naturally advocates the second alternative, and vigorously attacks Professor W. Bateson's considered, but to the medical mind surprising, dictum that when a new property appears in any individual of any species it is in reality not new, not an addition, but due to subtraction, namely, to the loss of some inhibitory factor which allows a primaeval property previously latent or recessive to become dominant. Pushed to its logical conclusion, this means, the lecturer argued, that the primal unit or units of protoplasm from which all living animal and vegetable forms have descended must have contained in a latent form the originals of every organ and every detail of the organs of all forms of life. Thus the leader of the Mendelians and Sir Ray Lankester—foemen worthy of his steel—will be in the lists against the Croonian lecturer, who by a review of the evolution of the infections and of the influence of environment on bacteria brings forward proof of the power of external factors to produce impressed variations in bacteria—for instance, to change a saprophytic into a pathogenic organism. He is, of course, fully aware of his opponents' objection that such modifications in unicellular organisms are irrelevant because there is no distinction between germinal and somatic matter, apart from which the concept of modifications is of no value (J. A. Thomson, 1912), and this contention he anticipates to some extent.

In the third lecture the argument is transferred to the consideration of adaptation in the higher animals to morbid agencies, and immunity, a subject with which biologists do not appear seriously to have dealt in this connexion, is brought forward as an illustration. There seems to be no reason to regard the production of antibodies as a persistence of a chance variation or as a primaeval property previously kept latent by an inhibitory factor now removed. The series of intercellular reactions and counteractions, constituting immunity, thus set in motion is not necessarily a temporary acquisition, as witness the period, after complete recovery from enteric fever, during which agglutinative changes may remain. This persistence or "law of habit" is also seen in metaplasia, neoplasms, and nervous tics. These considerations militate against the Batesonian hypothesis of evolution by progressive removal of inhibitory factors.

As to the inheritance of acquired conditions, it is pointed out, after allowing for the difficulties introduced in mammals by the intrauterine existence of the fetus and by other factors, that this may be direct or indirect. Instances of direct or identical inheritance are rare, and are confined to cases in which the influences affecting the body cells modify their internal secretions, and through these internal secretions so tell upon the germ cells and their metabolism as to set up similar defects and similar disorders of the internal secretions in the offspring—and here it need hardly be pointed out what an important influence hormones exert on growth; as examples of direct inheritance, the diatheses, the gouty and rheumatoid, are given. Regarding indirect inheritance, it must be remembered that the germ cells may be influenced by

factors involving the body at large; this is well shown by the effect on the offspring (high proportion of stillbirths) induced by plumbic, mercurial, and abrin intoxication of the father. The essential point in these observations is that as the mother is normal, no complications are induced by modifications acquired by the offspring while *in utero*.

Professor Adami insists on the importance of the chemical rather than of the morphological factors in heredity. The highly complex proteinogenous molecules of living matter or biophores possess inherent properties as an expression of their constitution, of the mode of linkage of the various nuclei, their number and the nature of their side-chains. This conception of the chemical constitution of living matter, and the recognition that function precedes structure and that environment leads to direct adaptation, should be substituted for the morphological hypothesis that individual properties are handed down by individual particles.

The abstracted form in which the lectures have necessarily so far appeared has not only the disadvantage inherent in the condensation of a close argument, but also that the charm of the lecturer's style is less obvious than usual. It is therefore doubly desirable that the lectures should be published in full. In the meanwhile it may be noted that biological authority is not entirely ranged against Adami's views; thus, in giving a rational account of the recapitulatory theory of development (in other words that the larval phase of development represents a former condition of the adults of the stock to which it belongs) Professor E. W. MacBride,¹ apparently independently, advocates adaptation from environment, and brings forward evidence from the new science of experimental embryology in support of the part played by hormones in connexion with the inheritance of acquired characters.

THE WAR EXHIBITION AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

IN May, 1915, the Council of the Royal College of Surgeons undertook to "preserve, classify, and register specimens forwarded from military hospitals." Towards the end of last year it became apparent to all who realized the educative value such a collection possessed for army medical officers that its display should not await the end of the war, and, as our readers are aware, the exhibition of pathological specimens was opened in the museum of the Royal College of Surgeons early this year. We were able to state last week that this has since been materially enlarged. The College can, at the present time, devote three of the largest rooms in the museum to the exhibition. Although in its scope it may be less wide than the collection now shown at Val-de-Grâce, yet it will be wide enough to include not only actual specimens of wounds of all parts of the body, and of the diseases and consequences of military wounds, but will also embrace samples of the missiles causing wounds, the various means of treatment adopted by military surgeons, and the results obtained so far as such results can be accurately represented by drawings, photographs, casts, and models. A valuable series of accurate pathological drawings is being collected from France, where Mr. A. K. Maxwell has been placed by the War Office and the Medical Research Committee for this special purpose. It is intended that every special department of surgery should be represented—orthopaedic surgery, plastic surgery, the treatment of face, mouth, and jaw deformities, of limb deformities, the fashioning of stumps, and the supply of artificial limbs. A special radiographic section is par-

ticularly desirable—one which will include radiograms of wounds in all parts of the body and at all stages of healing, as well as a series of radiograms showing the normal uninjured condition of all regions of the body, from all points of view. There can be no doubt that the material for such an extensive collection is already in existence, and it would be a grave mistake—a national misfortune—if steps are not taken now to gather into a whole what is at present scattered at various hospitals and institutions. So far as means and material are concerned, the realization of such a central or national exhibition offers no difficulty; the heads of the medical departments of the army have given everything that has been asked for the preservation and mounting of specimens, but in the matter of labour they have been unable to give any help. There is only the depleted staff of the museum to undertake a work which is very much greater than falls to the full staff in peace time. The aim, however, is to have a complete and extensive series of specimens ready for exhibition in the first week of next October. Meanwhile, the collection already displayed, which is open from 10 a.m. to 6 p.m. (on Saturdays to 1 p.m.), will well repay examination.

INFECTIOUS JAUNDICE.

IN America there have been a few epidemic or endemic cases of infectious jaundice; and though it has not been proved that they were due to the *Spirochaeta ictero-haemorrhagiae*, it appears probable that this is so from Noguchi's¹ recent observation that wild rats captured in America contain this organism in their kidneys, just as it has been shown that rats captured on the Western front in France, both in districts where the disease occurs in man and also at a distance from human cases, act as a "reservoir" for the spirochaete. Emulsions made from the kidneys of American wild rats were injected into guinea-pigs, and caused a typical ictero-haemorrhagic spirochaetosis exactly like that seen in guinea-pigs injected with the Japanese and Belgian strains of *Spirochaeta ictero-haemorrhagiae*. The attack of this spirochaete on the human body is probably a comparatively recent event, and it is suggested that the disease was originally epizootic among certain rodents, especially wild rats, and that after a long sojourn in these hosts its virulence for them has become so reduced that a state of tolerance for the spirochaete results. By means of a special technique Noguchi has for the first time cultivated artificially the Belgian and the American strains of the spirochaete, and by immunization experiments he finds that the Japanese, Belgian, and American strains are probably identical. Morphologically they are also identical, and present differences from other spirochaetes, so that a new genus should be recognized, for which the name *Leptospira*, on account of its fine and minute windings, is suggested. In commenting on the contrast between the mortality of 38 per cent. among the Japanese and of 3 per cent. among European soldiers, Noguchi points out that it is reasonable to assume that the Japanese strain has already acquired a marked increase in virulence for human beings, probably as the result of more frequent passage from man to man. Successive passage of the American strain through guinea-pigs increased its virulence. The results of further investigations will be published later. The discovery of this causal organism in American rats reveals a danger which remains latent as long as sanitary conditions are satisfactory.

TERRITORIAL À LA SUITE OFFICERS.

IN our issue of June 9th appeared a leading article on the position of medical officers who are *à la suite* of a Territorial general hospital. In this it was argued that the removal of these medical officers by the War Office for overseas service should not be carried out without

¹ MacBride: *Textbook of Embryology*. Edited by W. Heape. Vol. I. pp. 649-654. Macmillan, 1914.

¹ Hideyo Noguchi: *Journ. Exper. Med.*, Baltimore, 1917, vol. xxv, pp. 755-763.

consultation with the Central Medical War Committee, which alone is in a position to say, in each instance, who can be spared and who is indispensable for the needs of the civil community. A correspondent serving abroad in the Territorial medical force has read into this article an attempt to establish a special case for the *à la suite* medical officer of military age, and writes a long letter to rebuke us for championing this section of the medical profession at the expense of the ordinary Territorial medical officer, whose real and pressing grievances he accuses us of ignoring. We find it difficult to understand how any one could so misread our argument. In this article, as in those which came before and after, our principal concern was with the medical needs of the civilian population. So far from holding a brief for the *à la suite* officer, we suggested that proper co-ordination between the War Office and the central professional bodies would lead to the setting free of a number of these practitioners for service abroad without endangering the consultant or specialist attendance upon the civil population. We would remind our critic that under the original scheme for *à la suite* Territorial medical officers it was contemplated that these practitioners would be available for civil needs, although in khaki and in receipt of military pay. By accepting the imperial service obligation they placed themselves wholly under the War Office and outside the control of the Central Medical War Committee. There was thus no guarantee that their services would be retained when they were really wanted; hence our plea for co-operation between the Army Medical Department and the Committee. We understand, indeed, that the Army Medical Department has now agreed to inform the Central Medical War Committee whenever it is proposed to call up an *à la suite* officer for service away from his home; and that it will be open to the Committee to make representations in any case in which it seems likely that the treatment of the civil community will suffer as a result of the withdrawal of the officer from the civil side of his work. This reasonable understanding appears to offer a satisfactory settlement of a difficult question. As to the grievances of the ordinary Territorial officer, we are in full sympathy with our correspondent, and we are glad to see that the Naval and Military Committee of the British Medical Association has taken up this matter, and made strong representations to the Parliamentary Committee now sitting.

BABY WEEK, 1917.

THE first national baby week, which is now drawing to a close, was inaugurated on Sunday last by services at Westminster Abbey and in many churches. The movement has not been confined to the metropolis, and celebrations have been held throughout the three kingdoms. The Child Welfare Exhibition at Westminster, to which we refer below, was opened on Monday by the Queen, and has remained open throughout the week. On the same afternoon the Lord Mayor of London presided over a meeting for health workers at the Guildhall, at which Lord Rhondda, Mr. H. A. L. Fisher, President of the Board of Education, Mr. Hayes Fisher, the new President of the Local Government Board, and other speakers dwelt upon the need for a great national effort to safeguard the life of children and improve the conditions under which they are reared. Among provincial cities taking part in baby week, Liverpool has been particularly active, and a very full programme has been carried out under the patronage of the Lord Mayor and the Countess of Derby. In Dublin the arrangements were directed by a special committee in association with the Infant Aid Society and other organizations, and included a fête in Lord Iveagh's grounds on Wednesday afternoon. The exhibition organized by a number of maternity and child welfare associations at the Central Hall, Westminster, has been most interesting and instructive. Purely trade displays were

ruled out, with the result that each of the forty or fifty stalls had its own distinctive lesson to enforce in relation to the general plan. The largest single exhibit was an elaborate model, measuring forty square feet, of the maternity and infant department of the Royal Free Hospital, together with a more detailed reproduction of the nursing section. Another hospital exhibit was from the Infants' Hospital in Vincent Square, and illustrated feeding and nursing methods. The National Association for the Prevention of Consumption, in addition to a big display of photographs, had a model exhibiting side by side the well-kept and the slatternly dwelling. A gigantic reproduction of *Musca domestica*, measuring 15 ft. across the wings, was shown by the Women's Imperial Health Association, and at the same stand were fresh house-fly larvae and other microscopical specimens from the Lister Institute. Elsewhere demonstrations of breast and artificial feeding were in progress, and Dr. Eric Pritchard had also arranged a demonstration in the use of dried milk. Dental clinics, model infant consultations, nurseries and kindergartens, and minor ailment treatment centres, were also illustrated, the last-named showing first aid for children in cases of cuts and burns, the care of the teeth, and the care of eyes, ears, nose, and throat. These were undertaken respectively by the Queen Victoria's Jubilee Institute for Nurses, the School Dentists' Society, and the Scottish Union of Women Workers. Some of the London polytechnics illustrated their training departments for domestic science and hygiene; the Eugenics Education Society undertook the subject of healthy parentage; in fact, no side of infant life and care went without its ocular demonstration. The Exhibition Committee is to be congratulated upon an excellent piece of work.

AN EDUCATIONAL GARDEN.

THE somewhat novel experiment of using a private garden for educational purposes has of recent years been tried by Dr. J. B. Hurry at Reading. A number of plots have been laid out in his garden in which are grown a variety of plants used in industry and commerce. Series A includes plants used in medicine—for example, eucalyptus, belladonna, aconite, stramonium, gentian, liquorice, podophyllin, asafoetida, valerian, henbane, castor oil, cinchona, and the opium poppy. Series B includes plants used for food,—for example, maize, millet, sugar-cane, rice, bananas, arrowroot, ginger, chicory, pepper, olive, and cardamoms. Series C includes plants used for clothing and textiles, such as flax, hemp, cotton, jute, New Zealand flax, and ramie nettle. Series D includes plants that yield dyes, such as woad, indigo, madder, dyer's weed, turmeric, annatto, and alkanet. In the adjacent conservatories are exhibited more delicate economic plants, such as tea, coffee, soya beans, monkey-nuts, guava, chick-pea, cinnamon, and camphor. Next to the conservatories is a small museum in which are collected various products made from the above-mentioned plants, every article being accompanied by a descriptive label, so that the living plant can be studied in conjunction with the economic products derived from it. Every summer the garden, conservatories, and museum are thrown open free on several half-holidays to visitors, teachers, and the older school children of the borough, who in large numbers avail themselves of the privilege of seeing some of the important plants used in industry. A printed catalogue is supplied to every visitor, and from time to time demonstrations of the more interesting exhibits are given by Dr. Hurry and his assistants.

THE HALF-YEARLY INDEXES FOR 1917.

THE usual half-yearly indexes to the JOURNAL, to the EPITOME, and to the SUPPLEMENT have been prepared, and will be printed. They will, however, not be issued with all copies of the JOURNAL. Any member or subscriber who desires to have one or all three of the indexes can

obtain a copy of what he wants, post free, by sending a post-card notifying his desire to the Financial Secretary and Business Manager, British Medical Association, 429, Strand, W.C.2. Such copies will be dispatched shortly after the middle of July.

Medical Notes in Parliament.

Lord Hardinge on Mesopotamia.

VISCOUNT HARDINGE, who was Viceroy of India during the earlier operations in Mesopotamia, made his defence of his administration in the House of Lords on July 3rd. He dwelt on the multiplicity of calls made by the war on the Government of India: it sent an expeditionary force consisting of an army corps to France and Egypt, it sent two expeditions to East Africa, and finally was called upon to furnish an expedition to Mesopotamia. At the same time the North-West frontier of India between the autumn of 1914 and the end of 1915 was very disturbed, no fewer than seven serious attacks being made by the tribes. All were dealt with effectively, but it had to be remembered that at the most critical period of the war India was carrying out the largest military operations on the frontier that it had had to undertake since the frontier campaign of 1897. In addition, there was great unrest in India in the spring of 1915, traceable to the return to India from Canada and the United States of 7,000 revolutionaries, who initiated a campaign of murder and terrorism in the Punjab, necessitating the arrest in one week of no fewer than 3,500 revolutionary hooligans. Later on the German conspiracy to organize rebellion in Bengal and elsewhere, planned to break out on Christmas Day, 1915, was discovered, necessitating military preparations and naval patrols in the Bay of Bengal; and although this conspiracy was foiled by the arrest of the leaders ten days before the plan was to mature, at Christmas every officer, both military and civil, had to be at his post, and the troops in troop trains at the railway junctions ready for any emergency. He frankly and regretfully admitted that the medical arrangements in Mesopotamia, after the battle of Ctesiphon and during the retirement to Kut, and in later operations, disclosed serious shortcomings in the provision made. He shared the horror and indignation that the revelation of these sufferings had created, but in his own defence he said that information as to what was happening only began to trickle down to Bombay and Delhi during December, and he had proposed to send Lord Chelmsford and Surgeon-General MacNeece on a mission of inquiry. Lord Chelmsford did not go because it became known that he had been designated to succeed Lord Hardinge as Viceroy. As he was not satisfied with Surgeon-General MacNeece's report the Vincent-Bingley Commission was appointed. The heavy demands made upon India for the provision of ambulances and hospitals and their personnel in England, France, Mesopotamia, Egypt, and East Africa soon exhausted an organization never intended or prepared for operations out of India. Within three months of the outbreak of war the supply of hospital ships and of permanent hospital staff had been exhausted. Nevertheless, by making a great effort, many more ambulances, hospitals, and medical personnel were dispatched from India to the various theatres of war during 1915. It was principally due to the absence of sufficient river transport that the medical service on the Tigris broke down, but it was only in June and July, 1915, that the pressure first showed itself, and orders were then at once placed at home, but some delay occurred at the Admiralty in placing them. The Army Department fully realized the importance of river transport, and during the whole of the succeeding months strained every nerve to meet the demand. Ships and barges of shallow draught from every river in India, Burma, Shanghai, Hong Kong, the Nile, and even penny steamers from the Thames, were bought or commandeered, but a large proportion of them unfortunately foundered on their way to the Persian Gulf. All ready-built craft purchased proved ineffective in some way, while new construction in England was uncertain and subordinate to Admiralty demands. The situation could only have been met by preparations far in advance, which he considered the gradual development of policy in Mesopotamia did not

permit. Even in January, 1916, when there were only two divisions in Mesopotamia, the shortage of river transport was a serious obstacle to the efficiency of military operations, and this was greatly intensified when, within two months, the two divisions were increased to six, and the difficulties were increased when, as happened in the case of the two Indian divisions from France, the troops arrived without a large proportion of their ambulances, but, owing to military exigencies, were pushed up to the front without delay. He defended his use of private telegrams on the ground that the practice was established before his time.

Munition Workers.—In a speech in the House of Commons on June 28th, in which the Minister of Munitions, Dr. Addison, gave an account of the extraordinary development of that Ministry, the multiplicity of its departments, and the establishment and extension of munition works; he said that the Ministry was now responsible for the employment of over two million persons. He expressed the belief that in the rates of pay of women workers, which had risen from an average of 12s. a week to an average of 25s. a week, in the reduction of the hours of labour, in the introduction of more humane methods of employment, as well as in many other directions, the Labour Department of the Ministry had made an enduring contribution of high value towards the improvement of industrial methods. The employment of so many workers, especially women, away from their homes, raised social and other problems very difficult to deal with. It was not easy to obtain personal and tactful assistants of the right kind, but the Billeting Board was endeavouring to organize and direct local committees. The Government had assisted local authorities to provide permanent housing and had itself constructed temporary cottages or hostels. Great progress in the establishment of canteens had been made during the last twelve months, and altogether provision had been made for supplying meals to 810,000 persons daily at a cheap but self-supporting rate. Mr. Montagu congratulated Dr. Addison on the work accomplished, and Sir Worthington Evans, in a general reply, dealt with various points raised during the debate. It ended by the adoption of the vote for the Ministry without a division.

Pensions for Officers.—In reply to Colonel Yate, who asked when the new Royal Warrant enlarging pensions for officers would be issued, Sir Arthur Griffith-Boscawen said that he could only repeat the assurance that neither officers nor nurses would suffer any disadvantage from the delay, as the new warrant would operate from April 1st. It is understood that the differences between the Treasury and the Pensions Department are on only a few matters of detail in the scale and should soon be adjusted.

Recognition for Major Carter, I.M.S.—Mr. Chamberlain stated on July 5th, in reply to questions, that Major Carter, I.M.S., had suffered no injury, and would suffer none, in his career on account of the efforts he made to bring to notice and to secure a remedy for the deplorable defects in the medical arrangements in Mesopotamia. Mr. Chamberlain added that he was only waiting till copies of the report of the Commission could reach India to bring Major Carter's conduct to the notice of the Government of India with a view to his services receiving suitable recognition. He had been brought home in May, 1916, to advise as to the fitting out of hospital ships, etc., for Mesopotamia, and the War Office had informed the Government of India, who had applied for his services, that he could not be spared. He was granted the temporary rank of Lieutenant-Colonel on August 8th, 1916; he had held the rank of Major for three years previously. He joined the Indian Medical Service in 1902, at the age of 26.

The Sale of Morphine.—In reply to Sir William Collins, the Home Secretary said, on June 28th, that Regulation 40 B of the Order of Council, No. 501, of the 28th July, 1916, which restricts the traffic in opium and cocaine to that required for medicinal purposes, did not apply to morphine. The regulation was an emergency provision made under the powers of the Defence of the Realm Act, and he was not aware of any special grounds arising out of the present emergency for exercising those powers in regard to morphine. The inclusion of opium in the regulation was necessary in order to put a stop to the illicit export of opium in contravention of the proclamation.

Public Vaccination in Chester.—Mr. Hayes Fisher relieved the curiosity of Mr. Snowden as to the recent payment by the Chester Town Council of £112 7s. towards the salary of Dr. George Harrison, the public vaccinator, in respect of vaccination cases during four years ended September, 1914. The sum was an award in respect of vaccinations performed between April, 1910, and September, 1914. Awards to public vaccinators

had generally been delayed owing to the inability of the Local Government Board in present circumstances to make the necessary inquiries in the usual way.

Army Medical Re-examination.

EVIDENCE BEFORE PARLIAMENTARY COMMITTEE.

The House of Commons Committee on the Working of the Military Service Act, with special reference to the medical re-examination, began to take evidence on July 2nd. Mr. E. Shortt, K.C., presided.

The Director of Recruiting.

The Director of Recruiting (Brigadier General A. K. Geddes) was the first witness, and was in the chair throughout the sitting. He described the recruiting machinery as it had been increased during the war. At the beginning its capacity was only for the enlistment of 50,000 men per annum. The Registration Act of August, 1915, formed the basis of the military register. Men as they attested were marked off, but, as time went on, it got further and further out of date. He pointed to the difficulties due to changes of address and to persons bearing the same name. In Stepney subarea there were thirty-three Abraham Cohens, all of whom had changed their addresses since attestation. When the Review of Exceptions Act was passed, in May, 1917, there were approximately a million errors in the military register, and there was no plan to get that right. At the outbreak of war no precautions were taken to avoid trickery. Thus men unfit obtained papers marked rejected, and they could be sold afterwards to fit men at an average price of £15. There was evidence that medical cards had been forged, and false classification cards printed. Last August a plan was adopted by which no fewer than six million entries on the books had since been verified. But this was verification of entries, not of men; one million men who held rejection forms could not be touched. The intention for the future was to form a separate special department of the War Office to do the discriminating work. Deputy Directors of Recruiting had been appointed with charge areas corresponding to employment bureau areas. By getting the register up to date it was hoped that by the end of the year the machine would be absolutely right and sound. Colonel Galloway, Senior Physician to the Charing Cross Hospital, was appointed last December as the chief of a special branch at head quarters, which became responsible for advising in the arrangements of medical boards. Colonel Galloway and inspectors went about the country looking into medical board arrangements and advising doctors as to the standards of fitness. The standards which the boards now kept were much more uniform, fewer men were getting into the army who were unsuitable for the work to which they were allotted. The special medical examinations were carried out by the special board. Altogether he anticipated errors to the amount of 1 per cent., but that was including cases of impersonation. A man would go before a medical board and be classified. He would receive his calling up notices and a hopelessly unfit man would report in his stead. Thus they had a case of a man with two wooden legs reporting himself. Re-examinations were necessary. In illustration General Geddes referred to "doping" by recruits, remarking that in some cases everything had been done to make the work of the medical board difficult. The certificates of private practitioners had, in some instances, been a source of difficulty. A board would get a certificate, "I have examined John Smith," but there was not always the means of saying whether the person referred to was the one who came before the board. In the army there was room for men of lower class physique. There was no man able to make his living in civil life who could not find some employment in the army, but a man classified C 3 had no more chance of seeing the trenches than he would have if he remained in civilian life. In order to fill gaps caused by casualties the War Office had to get powers to approach men who had been in the service of the country. A good deal of public misapprehension existed as to the scope of these powers, but these were fully laid down in the Act. There had been organized opposition to re-examination. In some cases the men were not liable under the terms of the Review of Exceptions Act itself, or under the promise made in the House by the Under Secretary for War. It was true that notices had been sent to the dead; it was true also that men discharged and with the silver badge had been notified, but they had only to say they were ineligible and the matter dropped.

A member of the Committee asked General Geddes whether it was not a fact that medical boards, by marking

papers "R.R. two months" defeated the purposes of the Act, which said that no re-examination should take place under six months. The witness replied that if such were the case it would be so. Doctors could not be expected to be thoroughly cognizant of the Act, and no doubt they sometimes marked papers in ignorance. He doubted much if the recruiting officer would act in accordance with such markings. In reply to Sir Godfrey Baring, the witness acknowledged that recruiting sergeants had often exceeded, and sometimes ignored, instructions. He would personally honour a certificate given by a medical man who had attended a man for some time, but could place no credence on the word of a casual specialist called in at the last minute.

Sir Alfred Keogh, G.C.B.

The sitting of the Committee on July 3rd was occupied with the evidence of Sir Alfred Keogh. He explained the system of medical examination of recruits. When the war broke out every expert in the medical service had to be mobilized, and the system, under which medical inspectors of recruits were sent to centres at different times to see individual medical men so as to obtain a common standard, fell into abeyance. In November, 1914, the medical inspectors of recruits were restored, and by issuing instructions to every recruiting authority an endeavour made to check the disorder which undoubtedly existed. When Lord Derby suggested his group system of recruiting the opportunity arose of adopting a system of medical boards for examining recruits. A good deal must be allowed quite legitimately for negligence, and he had no doubt many men were passed who ought not to have been passed; but on the other hand, a great number of men were rejected who ought to have been passed under the category system. It was difficult to get medical practitioners to understand that a man who could do anything in civil life could do that thing in the army.

In answer to the Chairman, Sir Alfred said that if the president of a medical board disagreed with any member of the board as to the particular category in which a man should be placed he would express his dissent, and the general officer commanding the district would decide. On the question whether inquiries had been made into cases where rejected men had been found afterwards to be passed into B and C and sometimes into A classes, he said the differences might be due to the differences of opinion of the medical board; that, however, could not altogether explain the matter. Men who had been doing this work had become much more proficient. Whether that greater proficiency had led to more rejections or more acceptances he could not say. Invited by Mr. Pringle to account for a case in which it was said that the medical board had passed as fit 75 per cent. of the men who had previously been rejected, the witness could only attribute that to the increased efficiency of the board. No general instructions had been issued for lowering the standard. Occasionally there had been "round table" meetings of inspectors, but no record of the meetings had been kept. As a result of such meetings a letter would sometimes be sent to a board saying that there had been too many or too few rejections in a district, as the case might appear to be.

Mr. Nield called attention to an Army Council Order stating that no recruit who had at any time been under treatment for pulmonary tuberculosis should be accepted, and asked whether Sir Alfred would be surprised to know that a certain board always honoured that rule in the breach. Sir Alfred replied that he should certainly be surprised. Mr. Nield: Would you pass a man suffering from duodenal ulcer?—No. "Then," said Mr. Nield, "it would surprise you to know that such cases are being passed?" Sir Alfred Keogh agreed, and added that in the case of a man with duodenal ulcer coming before a board and evidence in the form of a certificate from his family practitioner being handed in, if any doubt existed as to the bona fides of the certificate, he would pass such a man with the idea of sending him into a military hospital for examination. Duodenal ulcer was most difficult to diagnose. Mr. Nield: What, pass him into the army and make him amenable to military law?—Yes, my idea being to get him into hospital. You cannot send a man into a military hospital unless he is in the army. Regarding reports as to the Gifford and Mill Hill boards, Sir Alfred, on a further question by Mr. Nield, said that if complaints were sent to him he would make recommendations to the Army Council, and might give instructions to his deputy to make inquiry as to the circumstances. If a board were found incompetent, action would be taken to bring about changes.

Colonel Galloway, C.B., A.M.S.

Colonel Galloway gave evidence on July 4th. He first gave an account of the constitution and working of the medical boards, mentioning that there are now 135 in England, Scotland, and Wales. The boards, as he found them when he entered upon his duties last December, might be said to have arisen in two or three ways. There were boards which evolved themselves from the old establishment of recruiting. In many cases the members were retired officers of the military services. Some were practically civilians, often having retired pretty early in life, and having identified themselves with the population around them. In other cases members were gentlemen who had long been out of practice. In a number of cases the boards had been chosen after consultation with the chairman of the Local Medical War Committee. Another sort of board was composed almost exclusively of officers, but in these instances it often happened that although all the members of the board were in khaki, they were Territorial or temporary officers and had civilian associations. Difficulties had been found in some areas in getting the accommodation required; private houses with a number of small rooms did not afford easy opportunity for consultations, and the enforced separation probably had something to do with complaints which were made. A medical board as a rule consisted of a president and four members. Frequently the president was a retired officer, but the number of presidents of this kind was becoming fewer as many of the older men could not stand the work. Their places were being taken in a number of cases by Territorial officers who had seen service at the front. Without reflection upon regulars, Colonel Galloway spoke of these doctors as exceeding suitable for the duty. He had tried the experiment of nominating two doctors who had no experience whatever of the army to undertake the presidency of board. In one instance the experiment was successful; but he did not think that this plan was advisable for general adoption. The duty undertaken by these doctors was purely patriotic and the rate of pay quite inadequate. The maximum rate for civilian doctors was £2 a day and only £1 was received for half a day's work. Colonel Galloway mentioned this in reference to the self-denying action of local practitioners who took turns often on alternate days or for parts of days while endeavouring to keep up their practices.

Colonel Galloway afterwards traced the formation of the special medical boards, which began with the establishment of an appeal medical board in London last September. Doctors of the very highest repute accepted this service. Cases began to be sent up in such number that this London board was nearly snowed under, and later in the year two other boards of a similar kind were created at Leeds and Edinburgh, and then a second board was set up in London. He next dealt with the method of examination adopted by medical boards generally. The first was a single medical examination by one member of the board, with such opinion as might be obtained from any other who might be a specialist; he then conferred with the president, and the two determined the classification of the man. The second method was the examination of the man by the full board, the members examining different parts and functions of the body in rotation. The president collated the information. Colonel Galloway was understood to indicate a preference for the latter method. But, speaking broadly, he said the difficulty of the medical profession in this matter of examination was that it had been asked by the War Office to perform an impossible task. In pre-war days they were asked to select fit men for the army; now they had also to take unfit men—for the lower categories. When the categories were limited to A, B, C, it was not so hard to make distinctions, but now the classes were further divided. In these circumstances he could not imagine two sets of boards agreeing continuously in their classification of the same men. They had not only to consider the present condition of a man, but also what it was likely to be in other circumstances—that is to say, what he could do. In regard to these matters, medical opinion had changed a good deal, and thus there was reason for variety. Moreover, it was necessary to remember, in noticing the differences of classification, various kinds of fraud—doping by recruits, the infection of sputa from other sources, and other frauds. Colonel Galloway acknowledged quite frankly that there had been numerous mistakes in diagnosis, but said he had been impressed by the general competence of the work of the boards. He attached great importance to certificates from a man's own medical attendant. Such statements of fact were valuable, but the witness did not attach the same importance to the certificates of specialists save in exceptional cases, his reason being that the board itself was

able to make its own examination, and therefore the opinion of a specialist upon one examination did not greatly weigh with them.

In reply to the Chairman, Colonel Galloway said that it was now his custom in making his inspections of medical boards through the country to walk in without any warning of his visit being given. The Chairman put it to the witness that he could hardly anticipate that faults which were charged against boards, such as haste and tearing up certificates, would be repeated in his presence. Asked if he had taken steps to have independent examination in a case of complaint, Colonel Galloway said that he did not do so at the beginning; he had advised that when opinions differed the man should be given the benefit of the doubt. In reply to a question as to whether medical boards examined as carefully in the case of re-examination as when a recruit came for the first time, the witness said that the re-examination, in view of the Exceptions Act, had been quite as careful, or even more careful, than formerly, owing to the difficulties encountered. Replying to Sir Godfrey Baring, Colonel Galloway denied that a president had the power to overrule other members of the board in a decision, but agreed that a certain latent power existed in a case of difference between the president and two members of the board. In answer to Colonel Grattan the witness said he had had occasion to make adverse reports, and that action had been taken by the War Office on these reports where necessary. In answer to another member of the committee, the witness added that he had taken notice of exhibitions of temper by members of the medical board even though they were under strain. He held, of course, that it was wrong for a president to classify without consultation, and he could not imagine that it was done. In reply to Mr. Pringle, he said he did not know of any instructions or understanding that in consequence of the change from open to trench warfare men of a lower standard could be classed "A." There had, however, in the nature of things, been a lowering of the standard. There had been a definite lowering in the eyesight standard.

Mr. Nield, K.C., and Mr. Sutton both put questions as to particular cases, and the witness intimated that he should be glad to have further particulars of these matters. Mr. Sutton, who was mainly concerned with allegations from Manchester, said he had already sent a mass of communications to the secretary. Colonel Galloway said he had seen a good deal of the working of the Manchester boards, and he considered that Mr. Sutton had been inaccurately informed when he said that the president had classified without consultation. Mr. Sutton retorted that Colonel Galloway could only speak of what took place when he was there. The witness took up readily a challenge as to the raising of the classification of recruits after they had been in training for a while. He maintained that it was thoroughly sound and right when, as frequently might happen, the condition of a man improved. Fresh air, training, or even the army kitchen might make a great difference.

THE Hon. Arthur Stanley, M.P., has been elected treasurer of St. Thomas's Hospital in succession to Mr. J. G. Wainwright. Mr. Stanley has been chairman since its formation of the joint committee of the British Red Cross and St. John Ambulance Association.

SILVER medals of the Royal Society of Arts have been awarded to Mr. F. A. Hocking, pharmacist to the London Hospital, for his paper on the war and our supply of drugs, and to Sir Arthur Pearson for his paper on the blind sufferers from the war and their future employment.

DR. V. H. RUTHERFORD has been appointed honorary secretary to the Wounded Allies Relief Committee in succession to Sir Lindsay Smith. Dr. Rutherford has already given valuable service in the organization of the committee's hospitals in France, Serbia, and Montenegro.

University College Hospital and the National Hospital for the Paralysed and Epileptic, Queen Square, London, have appointed a joint committee to manage a school of massage, etc., on behalf of the two hospitals. The school is situated in Queen Square, Bloomsbury, and has been named "The National Hospital and University College Hospital School of Massage and Electrical Treatment." The curriculum will include massage, remedial exercises, and medical electricity, and it is expected that the first term will commence early in October. There is a hostel in connexion with the school for the use of students who desire it.

THE MESOPOTAMIA COMMISSION.

[SECOND NOTICE.]

THE fact that the discussion of the Mesopotamia report in the public press and in conversation has turned so largely on the medical breakdown at a certain stage in the operations, and the further fact that, as Sir Victor Horsley anticipated, an attempt has been made in the interests of politicians to make a scapegoat of the medical services, render it necessary to go into some detail as to the origin of the military operations and their gradual extension.

The Parliamentary Commission, in speaking of Sir William Babbie's omissions in regard to the Mesopotamia campaign, says that they are all the more remarkable because of his promptitude and firmness in pressing war

provisions on the Indian Government necessary for the overseas expeditions generally, and they note that on the outbreak of war he urged the formation of a fleet of ocean hospital ships, the construction of hospital trains, and the extension of the Army Beaver Corps, a course already sanctioned before the war, although opportunity had not been found to carry it out. The Commission continues: "It may be that, as we have noticed in other phases of the expedition, Mesopotamia was in medical matters also regarded as a 'small side show,' and did not for that reason receive proper attention to its special and unique requirements." Here it is to be observed that at first there was good

reason for looking upon Mesopotamia as a "side show." India at the outbreak of hostilities was called upon to furnish three other expeditionary forces—A, to France and Egypt; B, a defensive expedition to East Africa; and C, an offensive expedition to East Africa. The position and strengths of these expeditions were settled by the end of September, 1914—that is to say, before the Mesopotamia expedition known as Force D was decided upon. India also had to repulse seven serious attacks on the north-west frontier between November 29th, 1914, and September 5th, 1915, and to deal with unrest in the Punjab early in 1915, and the German conspiracy to organize rebellion in Bengal at Christmas, 1915.

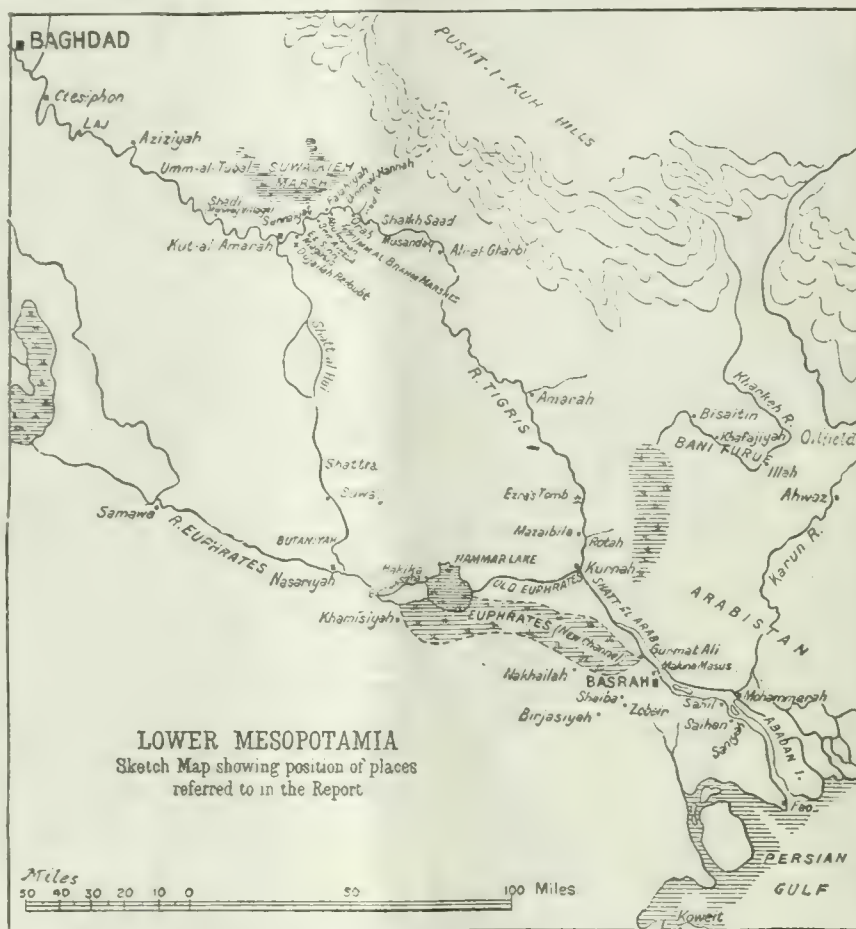

Mesopotamia, though etymologically it may be limited to the country between the Euphrates and the Tigris, really includes the country around the lower courses of these rivers for about five hundred miles, and also the whole of the course of the river Karun. The increasing German

influence in Turkey, overtly shown by the energy with which the Constantinople-Baghdad railway was pushed on, which, when complete, would have given direct railway communication between Berlin and Baghdad, was recognized as a menace to the British empire, and an agreement had been reached with Russia to divide Persia into spheres of interest, Southern Persia with the Persian Gulf coming under British influence. Great Britain had patrolled the Gulf for many years, and recently the Anglo-Persian Oil Company, with the support of the British Government, had established a pipe line from the oil fields among the foot-hills of the Pusht-i-Kuh along the left bank of the Karun river to Mohammerah, a port below Basra which could be reached by ocean-going steamers. The Euphrates and Tigris meet at Kurna; below that the waterway is

known as the Shatt-al-Arab, and the Karun debouches into the Shatt-al-Arab at Mohammerah, just north of the island of Abadan. The greater part of the country from the Gulf to near Kut-el-Amara is included in the vilayet of Basra, a town of some 80,000 inhabitants, at the head of the waterway for ocean-going ships. The original plan was to protect the oil installation at Abadan and the oil pipe line on the Karun river, but war with Turkey had been declared on November 5th, 1914, and General W. C. Barratt, who arrived in Mesopotamia on November 14th to command the expedition, was instructed by the Indian Government to go on to Basra if he con-

sidered his force strong enough. This he did, occupying the town on November 23rd, 1914, the Turkish forces retiring to Kurna, at the junction of the Tigris and Euphrates. The India Office in London thereupon advised an advance to Kurna, which town was occupied on December 9th. At that time the force consisted of one division (6th) with the equipment, including medical equipment, for a frontier expedition.

A threat on the oil pipe by Arabs reinforced by Turks—a threat which was carried out—induced the Government of India, under pressure from Whitehall, to send out reinforcements which eventually formed another division (the 12th), and the whole expedition was now reorganized as an army corps under General Nixon, who landed at Basra on April 9th, 1915. The Home Government was mainly responsible for the expansion of the operations and the increase of the force, the Indian Government for its equipment, and also for the instructions given to General

Distances by River: Sea to Basra 70 miles; Basra to Kurna 50, Kurna to Amara 90, Amara to Kut 150, Kut to Baghdad 212—Basra to Baghdad 502 miles; Kurna to Nasariyeh 68 miles. The channel from Basra to Kurna has a depth of about 7½ ft. of water in the dry season, but there is an extremely difficult piece of navigation in the narrows for 28 miles above Ezra's tomb. From Kurna to Amara the depth is about 4½ ft. in the dry season. From Amara to Kut navigation is easier, but from Kut to Baghdad the river is extremely tortuous, and not more than 3½ ft. of water can be relied on.

Nixon. The position at the beginning of April, 1915, was that the expeditionary force had its sea base at Basra, and its first line at Kurna, fifty miles up the river.

The Commission states that, though the force was doubled, the medical equipment sent to the last two brigades was not up to the authorized scale, and practically two divisions had medical equipment for only one, and that upon the Indian and not the British scale. Neither was there made such an addition to the river steamer transport as to bring its proportions up to the requirements of the increased forces. "These deficiencies," the Commission states, "do not seem to have had sufficient recognition by the Government of India."

General Nixon was instructed by the Commander-in-Chief in India not only to prepare a plan for the effective occupation of the Basra vilayet, but also a plan for a subsequent advance on Baghdad; he was instructed also to report on the need for a light railway, on mechanical transport, and on the adequacy of the river transport. These instructions were not communicated to the Home Government, and the Viceroy does not remember to have seen them; but at the end of May the Home Government accepted the Viceroy's recommendation that General Nixon should advance to Amara, 90 miles beyond Kurna. Then took place what was called "Townshend's Regatta," when, with a small force in boats of light draught converted into light armoured gunboats, the enemy was pursued, and, in spite of the sweltering heat and difficulties of navigation, driven from position to position, until on June 2nd General Townshend, with twenty-two sailors and soldiers, achieved the surrender of the garrison of Amara, consisting of 700 Turks.

Next, on July 25th, a successful expedition was made to Nasariyeh, a town 68 miles west of Kurna, a few miles above the spot where the channel called the Shatt-al-Hai, which communicates with the Tigris at Kut, opens into the Euphrates, after a course of over a hundred miles. Immediately afterwards, at the instance of the Viceroy and the Secretary of State, the Home Government agreed that the occupation of Kut itself had become a strategic necessity. The move northward began early in September, and Kut was entered by the 6th Division under General Townshend, after severe fighting, on September 29th, 1915.

The military operations of the previous three months had been extraordinarily successful, but they had been obtained after much hard fighting, and from the time the expedition moved above Kurna the river transport had been either insufficient or barely sufficient for its wants, and could not sustain additional pressure, yet the provision of the type of steamer and barge adapted to the Tigris had been delayed, and railway schemes had either been put on one side or not pressed by the Government of India. The chief of General Nixon's staff on July 10th forwarded a memorandum to the Government of India in which he enlarged on the risk of breakdown, and stated that the formation of a properly equipped river fleet was the special and most important need of the time; he, however, appears to have made no reference to the need for hospital steamers. Although it was known that it would have taken from eight to ten months to build river transport steamers and a further period to get them to Basra, so that under no circumstances could they have been available in Mesopotamia until towards the middle of 1916, the Indian Government only gave the order for them after a lengthy correspondence.

In July, 1915, the medical equipment was not up to its proper strength, even according to the low scale of Indian regulations, and the wounded and sick from the actions on the Karun river, at Nasariyeh and at Kut had been put to considerable discomfort through lack of ambulance transport, stationary hospital accommodation, and river hospital steamers, while the medical personnel was barely sufficient. All along, however, even in October, 1914, the Indian Government had contemplated an advance to Baghdad. As already stated, Sir Beauchamp Duff instructed General Nixon to prepare a plan for the subsequent advance on Baghdad; after the taking of Kut the proposal was much canvassed between India, Mesopotamia, and Whitehall. Both Whitehall and Simla proceeded on the assumption that Baghdad could be reached; the question with them was whether it could be held with the force then available against

expected reinforcements of the enemy; the soldiers on the spot wavered in their opinion. In October the War Cabinet at home was telegraphing to the Viceroy urging the great importance of the capture of Baghdad if it could subsequently be held. The War Office undertook to give two Indian divisions from France, but nothing more; in view of the "great need of striking success in the East" the advance to Baghdad was not only approved, but urged by the India Office at home. An extraordinary thing, however, is that though on October 21st Mr. Chamberlain in a private telegram warned Lord Hardinge of a possible concentration of 60,000 Turks in Baghdad in January, 1916, this information was not transmitted to General Nixon. The task of going on to Baghdad, if that move was to be decided on, would fall on General Townshend and the Sixth Division, which had already suffered severely from previous fighting and from sickness, so that British battalions were reduced to half their strength. General Townshend, an officer not wanting in enterprise, was reluctant to advance when he discovered that the enemy in front of him was reorganized; his reluctance was due partly to his insufficient and tired force, partly to the inadequacy of his transport, which had already failed him, and partly to the great length of his line of communications.

Nevertheless, some time early in November it was decided to advance without waiting for reinforcements, and Townshend concentrated a force of 11,000 effectives on the left bank of the Tigris at Laj, about nine miles below Ctesiphon. Although the Turkish forces at Ctesiphon consisted of 11,000 to 13,000 men in a strong line of trenches, the head quarters and administrative staff estimated probable casualties at 500 severely wounded; two river steamers—the *Mosul* and the *Jubbar*—were put on one side to be temporarily fitted up by Surgeon-General Hathaway for the reception of wounded, the arrangement being that the more seriously wounded were to be moved down to Kut in these vessels and the more lightly wounded taken on to Baghdad. The attack on the Turkish lines at Ctesiphon on November 22nd was partly successful. The next day (November 23rd) was spent in reorganizing positions captured and collecting the wounded, who on the two following days (November 24th and 25th) were evacuated to the river side at Laj. The casualties numbered 690 killed and 3,800 wounded. The enemy had been largely reinforced, and Townshend had to withdraw his force to Laj on November 25th, and then by stages to Kut, which he reached on December 3rd, 1915; the investment of Kut by the Turks began on December 7th, 1915.

The Parliamentary Commission adopts the opinion of the Vincent-Bingley Commission that the medical establishment at Ctesiphon was inadequate and the arrangements for collecting the wounded on the battlefield and accommodating them pending the evacuation of the river bank far from satisfactory. The last of the wounded were not got down to Laj until November 25th, and in the meantime many suffered from exposure, want of food, and inadequate attention, due to shortage of medical personnel. Save for two motor ambulances, no proper ambulance land transport was provided, and ordinary transport carts had to be used. In spite of this, however, the Parliamentary Commission recognizes that the evacuation of the wounded from Ctesiphon to Kut was a remarkable military achievement, carried out during a hazardous retreat against overwhelming odds, and with lines of communication threatened and at times cut by marauding Arabs.

It is reasonable, on the whole, to conclude that if there had been a sufficient number of hospital steamers at Laj the sufferings of the sick and wounded from that point downwards, though considerable, would have been, perhaps, no greater than are inevitable after an unsuccessful military operation. The two prepared steamers, however, could only accommodate a small proportion of the wounded; the remainder had to be put in any craft available, and so hurriedly that when vessels which had carried up animals were utilized there was no time to clear them of their accumulation of filth and dung. Surgeon-General Hathaway admitted to the Parliamentary Commission that the arrangements made "were absolutely inadequate, and that the wounded suffered intolerable discomfort," and Sir John Nixon agreed. Of the actual dispositions at Ctesiphon which were made by Colonel Hehir, the Parliamentary Commission expresses

the opinion "that having regard to the inadequate means at his disposal, we do not consider that his dispositions were open to serious criticism," wherein they differ from the Vincent-Bingley Commission. The Parliamentary Commission, however, goes on to express the view that Colonel Hehir should have taken more vigorous steps to report the shortages of medical personnel and equipment before both the battle of Kut and the battle of Ctesiphon.

THE WAR.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

CAPTAIN J. E. BRYDON, R.A.M.C.(T.F.).

Captain John Earnsleugh Brydon, R.A.M.C.(T.F.), died of gas poisoning on June 27th, aged 31. He was the fourth son of Mr. John Brydon, of Millburn, Darlington, and was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1908. After filling the posts of house-surgeon at the Bristol Children's Hospital and at Darlington Hospital he went into practice at Chagford, Devonshire. He took a commission in the Northumbrian Divisional Ammunition Column, Royal Field Artillery (T.F.), as lieutenant and medical officer on January 3rd, 1915, and was promoted to captain a year later. He was attached to the Yorkshire Regiment when killed.

CAPTAIN M. GREER, R.A.M.C.(T.F.).

Captain Morrice Greer, R.A.M.C.(T.F.), was reported as killed in action in the casualty list published on June 29th. He was educated at Liverpool University, and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1907. After filling the posts of house-surgeon of Leeds Public Dispensary, of assistant surgeon of Liverpool Dispensary, and of senior house-surgeon of the Liverpool Stanley Hospital, he went into practice at Corris, Merionethshire, where he was medical officer and public vaccinator of the Tallylin district of Dolgelly Union, certifying factory surgeon, and medical officer of the Post Office. He joined the 7th (Montgomery and Merionethshire) Territorial Battalion of the Royal Welsh Fusiliers as medical officer, with the rank of lieutenant, on July 21st, 1913, and had since been promoted to captain. He was attached to that regiment when killed.

CAPTAIN S. POOL, M.C., R.A.M.C.

Captain Samuel Pool, M.C., R.A.M.C., was reported as killed in action in the casualty list published on June 27th. He was educated at Liverpool University, where he graduated M.B. and Ch.B. in 1916, filling the posts of obstetric assistant at the Liverpool Maternity Hospital and house-surgeon of the Liverpool Royal Infirmary. He took a temporary commission as lieutenant in the R.A.M.C. in April, 1916, was promoted to captain on completion of a year's service, and was attached to the Leicestershire Regiment when killed. He received the Military Cross on November 27th, 1916.

Died on Service.

CAPTAIN A. L. M. CHURCHILL, R.A.M.C.(T.F.).

Captain Arthur Lindsay Maury Churchill, R.A.M.C.(T.F.), died on active service on June 24th. He was the son of the late J. F. Churchill, Esq., of the Department of Public Works, Ceylon, and was educated at Westminster Hospital, taking the diplomas of L.S.A. in 1895 and the L.M.S.S.A. in 1907. After serving as assistant medical officer at Wonford Hospital, and as pathologist and assistant medical officer of the County Asylum, Lancaster, he went into practice at Mervagissey, in Cornwall. He took a commission as lieutenant and medical officer in the 1st Hampshire (Southampton) Battalion of Royal Field Artillery (T.F.) on December 17th, 1914, and was promoted to captain on completion of a year's service. He was attached to the London Regiment at the time of his death.

CAPTAIN F. H. KNAGGS, R.A.M.C.

Captain Francis Henry Knaggs, R.A.M.C., died at Oak House, Huddersfield, on June 24th, aged 56. He was educated at Guy's Hospital, and took the diplomas of

M.R.C.S. in 1885, and the L.R.C.P.Lond. in 1887. After filling the posts of resident obstetrician at Guy's, clinical assistant to the ophthalmic department of Leeds Infirmary, and house-surgeon of Gloucester Infirmary, he went into practice at Huddersfield, till he took a temporary commission in the R.A.M.C. He was ophthalmic and aural surgeon to the Huddersfield Infirmary, and ex-secretary of the Huddersfield Medical Society.

CAPTAIN F. C. H. PIGGOTT, R.A.M.C.

Captain Frederick Cecil Holman Piggott, R.A.M.C., died suddenly at Sutton Veny on June 26th, aged 57. He was educated at Emmanuel College, Cambridge, where he held a foundation scholarship from 1878 to 1882, and graduated B.A., with second class honours, in the Natural Science Tripos in 1882, M.B. and B.C. in 1886, and M.D. in 1890, and acted for some time as demonstrator to the professor of physiology, and at St. Thomas's Hospital, taking the diplomas of M.R.C.S. and L.S.A. in 1884. He subsequently served as surgeon to the National Aid Society in the Sudan campaign of 1885, and for some time acted as British consul in the Eastern Sudan in that year, and received the Egyptian medal, with a clasp for Suakin, and the Khedive's bronze star. After acting as clinical assistant at the Hospital for Diseases of the Skin at Blackfriars he went into practice at Teignmouth, in Devonshire, where he was honorary consulting physician to the Teignmouth Hospital, medical officer of health of Teignmouth port and urban district, medical superintendent of Bitton Isolation Hospital, honorary medical referee for the Royal National Hospital for Consumption, Ventnor, and medical officer of the Post Office. He took a temporary commission as lieutenant in the R.A.M.C. in the latter half of 1915, and was promoted to captain on completion of a year's service.

Wounded.

Lieut.-Colonel R. H. L. Cordner, R.A.M.C.

Captain J. L. Baskin, R.A.M.C.(T.F.).

Captain C. H. Binney, R.A.M.C. (temporary).

Captain L. Campbell, R.A.M.C. (temporary).

Captain H. D. Clementi Smith, R.A.M.C.(T.F.).

Captain W. V. Corbett, R.A.M.C.

Captain G. F. Fawn, R.A.M.C. (temporary).

Captain A. Juett, Australian A.M.C.

Captain L. H. Skene, R.A.M.C. (temporary).

Captain A. J. Smith, R.A.M.C. (temporary).

Captain A. E. Sutton, M.C., R.A.M.C. (temporary).

Lieutenant V. T. C. Bent, R.A.M.C. (temporary).

Lieutenant J. S. Clark, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Barrett, C. R., Second Lieutenant Royal Field Artillery, second son of Dr. W. P. Barrett, of Folkestone, died on June 25th of wounds received the previous day, aged 26.

Compton, William Horace Gordon, Second Lieutenant Royal Field Artillery, eldest son of Captain W. H. Compton, R.A.M.C., of Brighton, killed June 17th. He was educated at Banister Court School, Southampton, enlisted in February, 1915, in the 3rd Home Counties (Cinque Ports) Brigade of R.F.A., was transferred to the Honourable Artillery Company, and got his commission in July, 1916.

Davy, Francis Lempriere, Captain, serving with the 47th Battalion, Australian Imperial Forces, killed on June 7th by the bursting of a high explosive shell while leading his company in an attack. He was the son of Lieut.-Colonel Henry Davy, C.B., of Exeter, consulting physician to the Southern Command. The commanding officer of the battalion writes that he died doing his duty like the soldier and the man he always was, and his loss is a heavy blow to the battalion he served so faithfully and well. His bravery on this and on many previous occasions was an outstanding feature. His loss is deeply deplored by officers and men. He had been recommended for his majority before going into action.

Goodall, Clarence William, Second Lieutenant 2nd South Staffordshire Regiment, aged 20, reported missing after the attack on Beaumont Hamel, November 13th, 1916, now officially reported killed, was attached at the time to the King's Liverpool Regiment, and was known to have been hit while leading his platoon against the German trenches. He was the second son of Dr. E. W. Goodall, medical superintendent, North-Western Hospital, Metropolitan Asylums Board, and was educated at Arnold House, Llandulas, and University College School, enlisted in the A.S.C. in January, 1915, and served in it till he went to the Military College, Sandhurst, in September, 1915. He was gazetted second lieutenant in January, 1916, and went to France with his regiment in July, 1916.

Gulland, Alexander Falkland, Captain the Buffs (East Kent Regiment), only surviving son of Surgeon-General Gulland, of Cheltenham, died of wounds on June 16th, aged 26. He got his commission on November 24th, 1914.

Lewis, Vincent James, Royal Field Artillery, eldest son of Dr. Lewis, of Twickenham, died June 20th, of wounds received on June 16th.

Menzies, William Alan, Second Lieutenant Royal Garrison Artillery, only son of Dr. J. A. Menzies, of Folkestone, killed June 14th, aged 19. He was born at Ootacamund, in India, in 1897, and educated at Rugby. He enlisted in the London Scottish in October, 1914, got his commission in January, 1916, and went to the front last Christmas.

Spanton, John Woodfield, Second Lieutenant Rifle Brigade, third and only surviving son of Mr. W. D. Spanton, F.R.C.S., of Hastings, formerly of Hanley, Staffordshire, died of wounds on June 13th. He was educated at Hereford School and at Cambridge, and was in practice as a solicitor at Leicester till the war began, when he enlisted in the Public Schools Battalion. He was wounded on April 26th.

Taylor, Philip Churton, Captain London Regiment, fourth son of the late Dr. Herbert Taylor of Kennington, reported missing on September 15th, 1916, now presumed killed on that date. He was educated at Aldenham School, got a commission on August 29th, 1914, went to Malta in September, and to France in January, 1915. He was wounded in February, 1915, became lieutenant in October, 1915, returned to the front in January, 1916, and was promoted to captain in June, 1916.

Underwood, George Milne, Second Lieutenant Royal Flying Corps, younger son of the late Dr. Underwood, of Kiukiang, China, previously reported missing on March 6th, 1917, and now as killed on that date, aged 19. He was educated at Merchiston School, and had entered Edinburgh University as a medical student. He joined the Royal Flying Corps last August.

Wall, Richard Ralph Baldwin, Major Royal Field Artillery, sixth son of the late Surgeon-General Thomas Frederick Wall, killed on June 8th. He was educated at Hermitage School, Bath, joined the army in 1899, and served in the Boer war, gaining the Queen's Medal with three clasps. He went out to France with the original expeditionary force.

Watson, P. G., Private, Royal Berkshire Regiment, elder son of Dr. S. G. Watson, of Southsea, and formerly of Brighton, killed in action.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

NOTES.

Captain R. H. M. S. Saundby, of the Royal Warwickshire Regiment and Royal Flying Corps, who has received the Military Cross in recognition of conspicuous gallantry in attacking and destroying an enemy airship, is the second son of Professor Robert Saundby of Birmingham.

England and Wales.

THE MEDICAL RE-EXAMINATIONS IN MANCHESTER AND SALFORD.

As the agitation about the medical re-examinations under the Military Service (Review of Exceptions) Act largely originated in Manchester and Salford, it may be of use to explain the procedure generally adopted there so far as the medical boards are concerned. The boards consisted, we believe, without exception of four medical men, the president being always chosen by the military authorities, and being either a colonel, major, or captain. In the choice of the other three members the Local Medical War Committees were consulted and asked to provide doctors; and as the committees found it impossible to obtain a sufficient number who could devote the whole day to the work a kind of rota was formed, some doctors undertaking to act every morning or every afternoon, while others could only attend one or two sessions a week; comparatively few gave their whole time to the work. But in practically every case the board consisted of four doctors who were expected strictly to keep their appointment or find a substitute, and only through some unavoidable circumstance was any board for a single sitting less than four in number. It is perhaps necessary to note that the medical boards had nothing to do with selecting what men should be medically examined. Complaints were frequently heard that men with perhaps only one arm or one leg, or cripples from birth, were summoned to be medically examined after, as it was asserted in some cases, ten or twelve previous rejections. So far as there may be any blame for causing such needless trouble the recruiting authorities are entirely responsible, as the medical boards had simply to examine all who were presented to them.

In most of the boards, by arrangement between the

doctors themselves, one of the three civilian doctors occupied himself chiefly with the recording of measurements and noting any defects of sight or hearing, dictating what he found to a clerk, who entered it on the medical history sheet. The recruit then passed to the second doctor, who noted identification marks, vaccination marks, general condition, and signs of any disease or cause of incapacity. Next the recruit went to the third doctor, who devoted his attention specially to the heart and lungs. In every board the three doctors were in close contiguity and frequently consulted together on doubtful points. The recruit then went before the president of the board, who had thus before him in writing all the essential facts found by the three doctors. It was definitely understood that the president alone had the right to determine the classification of the recruit, and was under no compulsion to consult the three civilian doctors, but on some boards the president distinctly requested the three doctors to write in pencil on the margin of the medical form what class they suggested for each person, and if the president disagreed he consulted with them, when there was a full exchange of opinions, and it was by no means rare for the president to defer to them. In other boards the president rather insisted on his right to decide the classification alone and less frequently consulted with the other doctors, simply reading the notes which they had dictated, doing any further examination which he thought necessary and at once deciding the class. Only in cases where the president decided on absolute rejection was it necessary for him to have the signature of the other doctors.

Complaints were made of the way in which recruits were treated, but it is to be remembered as a fact to be deplored, that 99 out of every 100 of the men were most anxious to obtain rejection, and in some cases resorted to every imaginable sort of trick to make themselves out as unfit for service. Without the fullest investigation little credit need be given to reports of rough treatment by examining doctors, though a degree of military brusqueness not understood might be shown by some of the presidents. When tricks to deceive the doctors were so common and often so easily exposed, to the evident chagrin of the trickster, it is hardly to be wondered at if at times some impatience were shown towards obvious malingering. Some of the men presented three or four private medical certificates, often of ancient date, detailing various diseases, some the merest trifles, elaborately expressed in medical terms, and some absolutely non-existent, and it is greatly to be regretted that a few doctors obtained a notoriety for the easy way in which they gave certificates exaggerating trifling ailments into disabilities. One will become almost classical, as it solemnly stated that the recipient was suffering from "paralysis of all the glands of the body." The cases certified as suffering from V.D.H. were very numerous, though in not a small proportion none of the four examining doctors of the board could find any trace of any form of heart disease or weakness. On the whole, however, certificates from civilian doctors were most helpful to the boards, and every attention was paid to them.

It has been repeatedly stated that the boards had instructions from the War Office what men to accept and what to reject, but a medical man who served on four boards informs us that he never saw or heard of any such instructions unless it be possible thus to describe a type-written document referring to various diseases, and stating how they might reasonably be expected to affect classification. This was of special value to presidents holding temporary medical commissions who had never seen active service abroad, but in no case did this document interfere with the unfettered discretion of the president to classify as he thought fit. It is of course impossible to assert categorically that no mistakes were made and no hardship entailed, but a close acquaintance with the work of the boards in Manchester and Salford satisfies our correspondent that except in one respect it would be difficult to imagine a system fairer all round. The one exception is that the presidents of boards should be instructed in every case to consult with the three civilian doctors and to defer to their unanimous opinion. It ought not to be possible for any president who may be so inclined to place a recruit in a high class when the other three doctors unanimously think he should be rejected or relegated to the reserve.

HOSPITALS AND THE CALLING UP OF DOCTORS.

Whilst President of the Local Government Board, Lord Rhondda received a letter from the President of Guy's Hospital referring to the effect on hospitals of the calling up of medical men. The governors of Guy's Hospital particularly referred to the difficulty in which hospitals with medical schools would be placed unless steps were taken to prevent further depletion of their staffs. Owing to the existing diminution in the personnel of hospitals and the small number of students available for rendering assistance, some specialists of military age were now carrying on almost single-handed the entire work of very important departments, which would have to be closed if these specialists were absorbed into the army. Lord Rhondda, in his reply, expressed the hope that the provision already made under the Military Service Act, 1916, would prevent any undue hardship being caused to these valuable institutions. He pointed out that the Committee of Reference of the Royal Colleges of Physicians and Surgeons had been set up for the special purpose of dealing with members of hospital staffs. After referring to Lord Derby's agreement not to grant commissions to doctors for the present except on the recommendation of the Central Medical War Committee, Lord Rhondda concluded: "Perhaps I may add that while I fully realize the patriotism exhibited by the medical and surgical staffs of the hospitals in their readiness to undertake military duties, I earnestly hope that specialists and others who are responsible for essential departments of the large hospitals—for example, the treatment of children's diseases—will carefully consider the claims of their hospitals and the importance of the work they are doing for the country. The maintenance of the health of the population at home is a matter of vital necessity."

WAR BREAD.

Dr. J. Campbell, at the request of the Metropolitan Committee for War Savings, has drawn up a preliminary report on "G. R." flour and war bread, with special reference to complaints as to palatability and digestibility. G. R. flour is wheaten flour (milled to 81 per cent.) mixed with products of such cereals as maize, barley, oatmeal, rye, rice, and bean flour. The mixture is usually made before milling. The non-wheaten cereals must be present between the limits of 20 per cent. and 50 per cent., but not more than 5 per cent. of beans is allowed. The wheaten flour present in the mixture contains much more of the berry than white flour. Owing to the presence of ferments acting on the gluten, G. R. flour does not keep so well as white flour, and is not so easy to bake, and the resulting loaf is of a close, heavy texture, with a comparatively high percentage of cellulose and of fibre. As the composition of G. R. flour may vary within such wide limits, it is easy to understand why war bread from different bakers shows marked differences in composition, palatability, and digestibility. Methods of baking have to be modified for the production of good war bread. Dr. Campbell is satisfied that many people, especially elderly persons, find war bread difficult of digestion. He considers it unsuitable food for the majority of old people, but for the young, and for the healthy adult, properly made war bread is nutritious, and if thoroughly masticated there is no undue strain on the digestive system. Among various improvements which he suggests, Dr. Campbell considers that an effort should be made to obtain greater uniformity of quality and properties in G. R. flour.

Scotland.

THE Carnegie trustees have promised a grant of £5,000 in aid of the advanced technical and higher education provided by the Royal Blind Asylum, Edinburgh, and made a further offer of £1 for every £1 (up to a limit of £5,000) raised otherwise. The trustees have also given a sum of £1,000 to defray the cost of stereotyping Braille plates. It has been resolved to increase the rate of board to children in the school from £20 to £30, and an appeal is made for subscriptions to meet maintenance expenses.

RECENT CASES OF SCURVY IN GLASGOW.

In a report submitted to the Glasgow Health Committee on June 27th the M.O.H., Dr. A. K. Chalmers, states that

during June a death from scurvy was registered as occurring in one of the Poor Law hospitals in Glasgow. Under normal conditions three or four cases of scurvy are admitted annually to each of the Poor Law hospitals (Barnhill and Merryflatts). Since the middle of February, however, 50 cases have been admitted, distributed thus:

February 15th to March 14th	2 cases.
March 15th to April 14th	7 "
April 15th to May 14th	15 "
May 15th to June 14th	22 "
Since June 15th	4 "
Total	50 cases.

The experience of these hospitals is that under ordinary circumstances in Glasgow the disease is confined to males, and not a single case in a female has been recognized in the present outbreak. The disease appears to be occurring only in men who are dwellers in model lodging-houses, or who live alone—a fact which suggests indifferent attention to the selection and preparation of meals. The Medical Superintendent of Barnhill is of opinion that the origin lies in the recent shortage of potatoes, this being the only form of fresh vegetable food which this class of patients is accustomed to prepare. From Dr. Liston it was learnt that the history of the Merryflatts patients conforms with this in more than half the cases, although in others it was not possible to ascertain that any alteration in diet had occurred over a prolonged period before the onset of symptoms. Apart from the lodging-house population occasional cases would appear also to be occurring among the general community, and the superintendents of the Royal, Western and Victoria Infirmaries state that several cases, seven in all, have been admitted for treatment since April, one of them from a rural district near Glasgow. Deaths from scurvy are now exceedingly infrequent in Great Britain. In Scotland in 1912, 4 were registered; in 1913, 3; and in 1915, 2; while in Glasgow during these years only one is known to have occurred.

Dr. Chalmers points out that the facts have a practical importance for the public at the present time. Potatoes have long been known to possess antiscorbutic properties. Their richness in starch has probably led to the too easy assumption that during the present scarcity an equivalent may readily be obtained from rice or other cereal also rich in starch. It was found, for example, that the Poor Law patients replaced the potato by bread, but neither bread nor rice have the antiscorbutic properties of the potato. These can most readily be obtained from fresh vegetables. All forms of fresh vegetables are valuable for the purpose, but cabbage has an established reputation for its antiscorbutic properties. Fresh vegetables, however, in some form or another are essential if the risk of scurvy is to be avoided, and where the ordinary forms are scarce a readily obtainable substitute, especially at the present time, may be found in the plentiful supply of young turnip plants which are being uprooted in singling, and which can readily be cooked much as spinach is.

Correspondence.

THE LATE DR. HACKMAN OF PORTSMOUTH.

SIR,—Will you allow us, on behalf of the Portsmouth Division of the Association, to bring before the notice of your readers the circumstances of the death of Dr. L. K. H. Hackman, late honorary secretary of the Division?

From the outbreak of hostilities to the time of his illness (epidemic cerebro-spinal meningitis) he was a civil medical practitioner doing duty at the Reception Hospital, at Cambridge Barracks, and attending the wives and families of soldiers resident in the town. There is little doubt that he contracted the disease in the discharge of his military duties.

Dr. Hackman was a devoted Association man; he did splendid service in the fight over the National Insurance Act, and as secretary of the Local Medical War Committee he was instrumental in recruiting about thirty men for the R.A.M.C.

The Executive of the Division decided to start a subscription for a memorial, the proceeds of which are to be devoted to placing his sons out in the world and eking out the slender provision he had made for his wife.

At the beginning of the war he had nine sons; one was killed at Neuve Chapelle, one was wounded at Vimy Ridge (the latter and three others are still serving in the ranks). A younger son has just passed out of Sandhurst and joined the Royal Flying Corps. An older son is a clergyman in Canada. One is an invalid, working, without wages, on a farm with a view to his restoration to health, and the youngest boy is just leaving school and entering as a probationer, without present salary, in a bank. Owing to the size of his family Dr. Hackman was able to save very little, and on account of the shortage of doctors Mrs. Hackman has been unable to dispose of his private practice except his panel which was not a large one.

The amount raised by the Division and Branch has reached nearly £530, but we do not expect to realize much more, and we venture to appeal to the profession for additional help.

Subscriptions may be sent to Mr. James Green (Brandon House, Mile End, Portsmouth), who is acting as secretary and treasurer to the fund.—We remain, etc.,

L. COLE-BAKER,
Chairman, Local Medical War Committee.
J. H. FREDERICK WAY,
Hon. Secretary, Local Medical War Committee.
T. A. MULCAHY,
Chairman, Portsmouth Division, B.M.A.
JAMES GREEN,
Honorary Secretary, Southern Branch.

Portsmouth, June 28th.

DYSENTERY AT GALLIPOLI.

SIR,—In a leading article of your issue of June 2nd, 1917, entitled "Dysentery at Gallipoli," occur certain statements and inferences, with regard to the relative incidence of amoebic and bacillary dysentery in that area, on which we would desire briefly to comment.

The acute dysentery of war has, as you state, been usually regarded as predominantly bacillary, and from our experience of, and observations on, this disease during the present war in all the Eastern fronts, including Mesopotamia, we can state with some assurance that the collected data from various laboratories in the East will, when published, indicate an overwhelming preponderance of the bacillary form, constituting probably 80 per cent. or more of all the acute dysenteries. With the ever-increasing laboratory organizations in the Eastern fronts and the introduction of protozoological experts, the extent of the participation of pathogenic entamoebae in the causation of acute dysentery has been very precisely defined, and there is no evidence that they have been responsible for more than 20 to 25 per cent. of the acute dysenteries in any area, and generally for much less. Nor, in our opinion, did the Gallipoli dysentery form any exception to the rule.

While granting that the worker at home is at a disadvantage from the fact that convalescents mainly come under his purview, the fact remains that expert bacteriologists and protozoologists in London found no evidence of a preponderance of amoebic infections from that area. Only about 10 to 15 per cent. of these convalescents were found to be infected with amoebae, and this figure includes probably a large proportion who were merely carriers and had never exhibited the classical symptoms of dysentery. Had the cases examined in London with negative results been originally infected with amoebae, then the emetine as given at Gallipoli must have had a much higher sterilizing effect on amoebae than it has since proved to have. The results obtained at home from cultural and serological tests indicated, indeed, that the dysentery bacilli had been responsible for at least 50 per cent. and perhaps more of the dysentery infections.

Archibald, Hadfield, Logan, and Campbell concluded from observations on the spot that the amoebic form was the predominant, if not the only form, during the period July to October, 1915, and that subsequently the type changed completely to bacillary. Yet the convalescents returning to England during the first period did not show a higher percentage of *E. histolytica* infections than those returning later from Egypt, where amoebic infections were undoubtedly very much fewer than bacillary.

The discordant opinion with regard to the nature of the Gallipoli dysentery, especially during the period May to October, 1915, finds a parallel in our experience in Mesopotamia.

During our stay there special inquiry in various parts of the area showed that amoebic dysentery formed only 15 per cent. of all the true dysenteries. Yet the examination of dysentery convalescents in India produced the impression that the amoebic was the predominant type in Mesopotamia, and it is just possible that the examination of Gallipoli convalescents in Egypt during the closing months of 1915 and the early part of 1916, produced a similarly erroneous view of the nature of the Gallipoli outbreak. It was at this period that the lack of trained protozoologists was chiefly felt, and it would be rather a strange coincidence if with the arrival of these experts the type should suddenly have changed to bacillary.

With regard to the use of emetine, which was advocated in every case of dysentery at that time by Sir Ronald Ross, we feel that probably there was some justification for the recommendation, considering the difficulties then involved in securing accurate and extensive laboratory diagnoses. It would be a grave disservice, however, to suggest the reintroduction of any such unscientific procedure.

You refer to the view expressed by Captain Bartlett that the Gallipoli dysentery was primarily amoebic and that bacillary infections when present were superimposed on, or predisposed to by, some primary amoebic infection. So far as we are aware, there are no facts to support a generalization of this kind, though the occurrence of mixed infections has long been recognized, as also the facts that amoebic ulcers may be secondarily infected with bacteria and that amoebic ulceration is not infrequently found *post mortem* when there has been no indication of this disease during life.—We are, etc.,

J. C. G. LEDINGHAM, Lieut.-Col., R.A.M.C.
C. M. WENYON, Lieut.-Col., R.A.M.C.

London, June 18th.

SIR VICTOR HORSLEY'S OPINION ON MEDICAL ARRANGEMENTS IN MESOPOTAMIA.

SIR,—In your sympathetic reference to my husband, Sir Victor Horsley, and to his letter to you on the subject of the medical breakdown in Mesopotamia and in India, you bear testimony to the exactness of his summary of the facts, and you draw a certain inference from his remarks—namely, that he feared there would be an attempt to make the medical service the scapegoat to bear the sins of the other departments. In the light of his letters and diary I do not think this inference, otherwise a perfectly possible interpretation of his words, at all expresses his real views.

The facts of the medical situation in India were to his eyes so glaring that, in the short space of time of his stay there (hardly a fortnight) he was able to put his finger on practically all the points since published by the Parliamentary Commission, and his fear was not that the medical service as a whole, nor the authorities in that service, would become the scapegoat for others, but that the case of the local medical officers in Mesopotamia would suffer for results produced by causes for which they were not responsible. The point is of importance, and I hope therefore you will allow me the opportunity to express what I know to have been his view of the situation.—I am, etc.,

London, W., July 4th.

ELDRED HORSLEY.

QUO VADIS (VEL CUI BONO)?

SIR,—Doctors who went through the conflict in 1911 and 1912, guided by their political instinct to follow the windings of political intrigue, must be alarmed by renewed signs of divided counsels in the profession. Each of us is entitled to his own opinion as to the burden of blame for past failure only if that opinion be in accordance with the facts. The statement in Dr. F. J. Smith's letter that

Extra remuneration was sufficient to cause the defeat of the avowed and official policy of the Association through its sufficiency to tempt the weaker brethren to break their pledge

is entirely misleading. The actual cause was quite different. Mr. Lloyd George and his subordinates made no secret of the fact that they had a whole time State Medical Service scheme and the necessary staff ready to work it, in the event of a medical "strike." The ignorant said this was mere bluff; the well informed knew it to be true, and happily the information was sufficiently diffused

to demonstrate the futility of resistance. Judged by any moral standard, the real "weaker brethren" were those who stealthily sought appointments in a prospective State Medical Service, and had everything to gain, not the men whose capital was already invested in a practice and had everything to lose. Let Dr. Smith be just to the panel practitioner. It is not fitting that a member of the Council which directed the policy of the Association in 1911 should impute blame to others.

No useful purpose can now be served by recrimination. The errors of the past may serve as warnings for the future. Dr. Smith is on surer ground when he describes the Association's new plan of campaign "as a strike, though it is disguised under the name of a general refusal on the part of insurance practitioners to renew their contracts." The panel practitioner is not likely to play the game of the enemy in any such simple-minded way. We have already found that the enemy is within our gates, and no partial "strike" of the profession could be otherwise than disastrous to the strikers. Medical men do not readily combine for any object of common interest, and the project of combination in the form of a trade union is doomed from the outset, because the essential condition of effectiveness, namely, the disciplinary control of the entire body of registered medical men, cannot be secured by any known means.—I am, etc.,

Cambridge, July 2nd.

B. E. FORDYCE.

THE CO-ORDINATION OF BRITISH MEDICAL POLICY.

SIR,—In your issue for June 23rd appears a letter signed W. Coode Adams, which commences, "As an active and loyal member of the British Medical Association." I believe Dr. Coode Adams is the president of the Panel Medico-Political Union, whose honorary treasurer has recently announced his resignation because of that union's campaign against the Association. In the *Medical World* and in all his published speeches Dr. Adams does everything to prove (to his own satisfaction) the utter incompetence of the British Medical Association and of all who are responsible for its policy, thereby seeking to unsettle its members and to transfer their allegiance to his pet union.

I suppose we must remember that "faithful are the wounds of a friend"; but for a new interpretation of what is usually understood to be conveyed by the words "active and loyal" we must feel ourselves very much indebted now to Dr. W. Coode Adams.—I am, etc.,

Hove, June 30th.

E. ROWLAND FOTHERGILL.

SIR,—It has frequently been said, and again lately by Dr. Fred. J. Smith, that the Association failed the profession in the matter of the Insurance Act, and that the weaker brethren accepted the Act when given a bribe. This is not a true presentment of the case. I, and many others, recognized that a very effective attempt was being made to better the conditions of club practice; and even if I lost somewhat I was quite prepared to forego something in order to better the lot of others who were, by local conditions, bound to engage in that kind of work. When, as the result of the opposition of the Association, better terms were obtained I was ready to accept the conditions proposed. As to the financial result of insurance practice, I think I am rather better off than I was before, though the difference is not considerable. But the conditions under which I work are more favourable. I hate book-keeping and sending out accounts, and I have much less of that to do under the insurance scheme. The clerk finds out what I have earned and pays me. I never question the amounts. But far more agreeable is the being able to treat cases effectually. I am able to give as much medicine as the patients require without considering the cost to them, and to see them as often as I think desirable free from any suspicion of piling up a bill. I am not aware of any moral deterioration so far.

As to the future, no doubt there will be alterations, some of which may press hardly on us. We may not be fairly treated, and we may have new duties thrust upon us. As long as they are not too suggestive of the three-legged stool and statistics I can await their development without much anxiety.

As to whether proposed changes can be best met by the Association or by trade unions, I would again point out

that the Association already possesses the confidence of politicians. They refer matters to it, and they seek its advice, because the Association represents as nothing else does the whole profession, both that part which works under the Acts and that part which is not affected by them. Any union formed by insurance practitioners in their own interests is out of court at once. They are the opposition. It is of no use consulting them; they are to be bridled. Moreover, trade union methods can never be employed by us. Picketings, peaceful or otherwise, cannot be used by us; nor can we leave the sick poor of any locality untended for a week or a fortnight while we and the administrators are wrangling over the inclusion of dependants of the insured or persons "broke in the wars."

What we have to consider seriously is how to stimulate the apathetic, to make them members of the Association, and to induce them when they are members to attend the Divisional and Branch meetings. When out of a Branch membership of about 150 only some 20 or 30 attend any meetings, there is cause for self-examination.

We must make our meetings attractive, and we must show that we value fellow members more than the man in the street. Whatever we do, let no one mention the word reorganization. No alteration to a more democratic, or, preferably, to a more oligarchic form, will infuse keenness among the apathetic. Personal influence alone can effect that.—I am, etc.,

Bournemouth, July 1st.

GEORGE MAHOMED.

Obituary.

SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., M.D.

SIR GEORGE BIRDWOOD, who died at Ealing on June 28th, in his 85th year, was a remarkable man, not only by reason of his learning and what he accomplished, but through the geniality, generosity, and eagerness of his temperament. He had a solid knowledge of the natural products of India, of the art and history of its peoples, and a fund of curious information which made it a maxim of the India Office when a puzzling question of fact or custom arose to "ask Birdwood." He was not less ready to help inquirers who had no special claim on him, and there were two advantages in asking Birdwood: the first was that nine times out of ten he knew, and the second that if he did not he said so frankly. But, with all this, his name might have been unknown by any save a few officials and specialists had he not possessed a clear and lively style and a sprightly humour which brightened all he wrote.

He came of a family which has been for four generations connected with India, and has in this generation produced General Sir W. R. Birdwood, who commanded the Australian and New Zealand troops at the Dardanelles. George Birdwood was born at Belgaum, in the Deccan, the eldest son of General Christopher Birdwood. At the age of 7 he was sent to Plymouth, the home of his family, and went to the New Grammar School there and afterwards to Edinburgh, where he graduated M.D. in 1854. In the same year he entered the Bombay Medical Service. He spent some years in military employment, and served in the *Ajdaha* frigate in the Gulf during the Persian war of 1856-7, receiving the medal and clasp. In the spring of 1857 he was appointed professor of anatomy and physiology in Grant Medical College, Bombay, and afterwards held the chair of botany and materia medica. His sympathy with Indian aspirations made him the interpreter of native opinion to the Government, as he was later in life to the home public. With the help of Hindu and Parsee merchants he reconstituted the Bombay Central Museum at the Victoria and Albert Museum at a cost of over £200,000, and produced a *Catalogue of the Economic Products of the Presidency of Bombay*, which has served as a model for other similar publications. Owing to a breakdown in health he came home in 1868, but in the following year was entrusted with the task of organizing a series of special exhibitions of the Indian collections at South Kensington. In 1871 he was permanently appointed to do such work at the India Office, but he soon went beyond this, and his report on the old records in the office led to the reconstitution of the Records Branch, and to the institution of a serial publication in which such records

have since been printed. Birdwood arranged the exhibition of the presents received by King Edward VII when, as Prince of Wales, he visited India, and in 1878 he organized the Indian Section of the Paris Exhibition of that year; he wrote a *Handbook* for the section, and later on handbooks to *The Industrial Arts of India*, and *The Arts of India*. He contributed many articles to learned societies, but his real work as a writer was to explain India to the rest of the British empire, and perhaps a little to itself.

He received the C.S.I. when Queen Victoria was proclaimed Empress of India (January 1st, 1877), and the K.C.I.E. in 1881; Cambridge gave him the honorary LL.D. in 1886.

EDGAR ATHELSTANE BROWNE, F.R.C.S. EDIN.,

M.Ch. LIVERPOOL,

CONSULTING SURGEON TO THE EYE AND EAR INFIRMARY; LATE LECTURER IN OPHTHALMOLOGY, UNIVERSITY OF LIVERPOOL.

It is with great regret that we have to record the death of Mr. Edgar A. Browne, which took place on June 27th at West Kirby, where he lived after retiring from practice over a year ago. He had been declining for some months, and his end was not unexpected, having reached his seventy-sixth year. The loss of this distinguished member of our profession is a severe one; many of his friends had hoped that his relinquishing active practice would herald for him a serene old age, and have preserved him to us for many a year. Mr. Browne's father, Hablot K. Browne, was "Phiz," the artist who illustrated some of Dickens's earlier works. Of Huguenot extraction, Mr. Edgar A. Browne was born in London, educated at a school of which the father of the celebrated Rowland Hill was principal. Mr. Browne met many famous Victorian writers at his father's house, and his recollections and impressions were published in a work under the title *Phiz and Dickens* in 1913. He began the study of medicine at St. Thomas's Hospital, took the diplomas of M.R.C.S. and L.M. in 1864, of L.S.A. in 1865, and shortly afterwards settled in general practice in Liverpool. He was a demonstrator of anatomy with Dr. T. R. Glynn at the School of Medicine, and was appointed surgeon to St. George's Hospital for Skin Diseases and assistant surgeon to the Eye and Ear Infirmary. At that time it would appear that there was nothing incongruous in a young man devoting his energies to more than one speciality. Evidence of his ability and powers of accurate observation is to be found in papers published in 1870 in the *Liverpool Medical and Surgical Reports* on eczema and on early stages of syphilis as affecting the skin. When the new Liverpool Eye and Ear Infirmary was built, Mr. Browne's energies were wholly devoted to the diseases of the eye, and he held the post of honorary surgeon for many years, and in 1884 succeeded Mr. Shadford Walker as lecturer on ophthalmology at the university, and only a few months ago resigned the post. In 1886 he became F.R.C.S. Edin., and as a recognition of his academic worth he received in 1907 from the University of Liverpool M.Ch. *honoris causa*. Mr. Browne contributed many papers on eye diseases to the *Liverpool Medico-Chirurgical Journal*. He wrote an excellent practical book, entitled *How to Use the Ophthalmoscope*, which has run through many editions, and, in conjunction with Dr. Hope, published a *Manual of School Hygiene*. Mr. Browne was a member of the Ophthalmological Society and of the Société Française d'Ophthalmologie, and many of his writings are to be found in the transactions of these societies. He was president of the Dickens Fellowship (Liverpool Branch), and those who heard him speak at the meetings or read extracts from the great author's works thoroughly enjoyed the experience. He was president of the Liverpool Medical Institution 1900-2, and delivered two addresses during his period of office—"Theory and Science" and "Intellectual Aspects of Medical Knowledge," which attracted a good deal of attention outside medical circles. In March, 1916, he celebrated his jubilee of membership of the Medical Institution, and numerous friends were present to honour him.

Mr. Edgar A. Browne was a lovable man; he attracted by his personal worth men famous in literature, art, and science. In literature and art his opinion was gladly sought by those whose high aim is to foster these amenities of life in a large commercial centre like Liverpool. He enjoyed life as a spectator, appreciated alike the good

points of man and his foibles, which he often caricatured with his ever ready pencil. His humour was of the brilliant type never sardonic, and if sometimes tinged with irony it was never mordant. All his intimate friends must have at one time or another realized that he could detect and humorously exhibit their little weaknesses in caricature. As a lecturer not only did he make his subject matter live, but he embroidered it with ornaments of speech, and gave it finishing touches of humour.

Mr. Browne was twice married, and by his first marriage had four sons and two daughters. Of these three sons survive; the eldest, Hablot J. M. Browne, is a well-known practitioner in Hoylake. His second wife survives him. A representative gathering of medical men, friends, university colleagues, members of literary and artistic circles were present at the funeral service held at St. Margaret's, Prince's Road, on June 30th.

We regret to record the death of Dr. C. T. EWART, who was temporarily appointed last September to the post of medical superintendent of the London County Council's Asylum at Claybury, of which he had been senior assistant medical officer. After studying at the Universities of Aberdeen and Edinburgh he graduated M.B. and C.M. Aberd. in 1878, and proceeded to the M.D. degree in 1892. His career was bound up with asylum work, for which he had in a high degree the special qualities of mind and disposition which make the successful medical officer to a large institution. In spite of a philosophical tendency of mind, which found expression in a number of contributions to serious reviews, he was one of the earliest to draw practical attention to the value of special industrial colonies for the epileptic, and may be correctly described as the originator of the scheme adopted later by the London County Council when the colony for the insane epileptic was founded at Epsom. He was the first to institute the training of nurses in the London asylums on the basis of the syllabus of the St. John Ambulance Association. He took the greatest interest in physical drill for mental patients, many of whom in asylums need encouragement to perform muscular movements, especially those of a general, orderly, and sustained kind. He was deeply interested in all things pertaining to the welfare and comfort of the insane. In his dealings with the patients he showed unfailing sympathy and kindness, never turning a deaf ear to the most trivial or unreasonable complaint. He was an ardent naturalist, and skilled in many branches of athletics. In private life he was greatly loved by colleagues and friends, from one of whom we have received a glowing account of the charm and sincerity of his character. Dr. Ewart married, whilst at Claybury, the daughter of the late Mr. Abraham Flint, who, with one daughter, survives him.

Universities and Colleges.

UNIVERSITY OF MANCHESTER.

THE following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—Mercy D. Barber, W. T. G. Boul, Hilda K. Brade, Frances G. Bullough, Kathleen L. Cass, Ruth E. Conway, J. Holker, N. Kletz, E. N. P. Martland, A. B. Platt, J. Shlosberg, D. M. Sutherland, H. Taylor.
Medicine.—C. F. J. Carruthers, Elizabeth C. Powell.
Surgery.—Elizabeth C. Powell.
Obstetrics.—C. F. J. Carruthers, J. C. T. Fiddes, R. S. Paterson.
Forensic Medicine and Toxicology.—T. H. Almond, Sybil Bailey, Mary G. Cardwell, J. Charnley, J. C. T. Fiddes, F. L. Hean, J. Mills, Kathleen O'Donnell, M. C. Paterson, Harriet R. L. Reid, Norah H. Schuster, L. J. Schwartz, V. T. Smith, Marie Wardman.

* Recommended for distinction in Medicine and Surgery.

† Recommended for distinction in Medicine.

UNIVERSITY OF SHEFFIELD.

THE following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—Winifred H. Wells (with first-class honours and distinction in medicine and surgery), Annie Clark, Ethel M. Mathews.

The Kaye scholarship has been awarded to Dorothy E. Mathews, and the Clinical Gold Medal to Winifred H. Wells.

UNIVERSITY OF ST. ANDREWS.

At a meeting of the General Council of the University of St. Andrews on June 30th a report was received from a committee recommending the institution of a degree in commerce, and urging the establishment of a chair or lectureship on colonial and imperial history, and arrangements for teaching Italian, Spanish, and Russian. The committee also recommended that it should have powers to urge the claims of the university to subsidies from the Government or any other body for the development of research work, now hindered by the reduction of the Government grant. The Council referred the report to the University Court for its favourable consideration. At the same meeting Dr. W. Barrie Dow (Dunfermline) was re-elected an assessor on the University Court, and it was announced that the following had completed all the examinations for the degrees of M.B., Ch.B.:

Sheila Bridgeford, Annie R. Campbell, F. J. Carlton, Mary I. S. Cuthbert, J. Irvine, J. Kinnear, A. M. MacGillivray, Flora M. Macdonald.

UNIVERSITY OF DURHAM.

At the convocation held on June 26th the following degrees were conferred:

M.D.—W. Hudson, N. F. Rowstron.
M.D. (*For Practitioners of Fifteen Years' Standing*).—J. V. Arkle, E. Down.
M.B. AND B.S.—P. V. Anderson, G. A. Clark, W. Duncan, E. C. Dunlop, M. J. Hilton, R. Hunter, C. G. Irwin, H. M. Leete, Phyllis Marriott, Freda Newman, T. W. Shaw, Sadek Abdel Shheid.
D.P.H.—W. E. R. Saunders.

The Services.

INDIAN MEDICAL SERVICE.

Promotion in India.

A CORRESPONDENT calls attention to the circumstance that a recent order with reference to the promotion of officers of the Indian army, sanctioning the promotion of a second lieutenant to lieutenant after one year's service, the promotion of a lieutenant to a captaincy after four years' service, and of a captain to a majority after fifteen years' service for promotion, does not apply to the Indian Medical Service. Previous to this order an officer in the Indian army received his majority after eighteen years' service for promotion and an officer in the Indian Medical Service after twelve years' service for promotion, because the latter was allowed an average of six years' study as an undergraduate. As a result of this order and the refusal of its application to the members of the Indian Medical Service, it follows that a combatant officer with eleven years' service as a captain becomes senior to an I.M.S. man who previous to the order was senior to him.

Medical News.

SIR GEORGE NEWMAN, Chief Medical Officer of the Board of Education, has joined the committee appointed by the President of the Board of Agriculture to investigate the production and distribution of milk.

SIR MALCOLM MORRIS has been elected president of the Institute of Hygiene in succession to Sir William Bennett, who has held the post for the past ten years, and will continue his association with the institute as vice-president.

AMONG the civil list pensions granted in 1916-17 are awards to Mrs. Charlton Bastian of £100, in consideration of the services to science of her late husband, Dr. Charlton Bastian, and of her straitened circumstances; and to Mrs. Minchin of £75, in consideration of the scientific work of her late husband, Professor E. A. Minchin, and of her straitened circumstances.

THE Harben gold medal of the Royal Institute of Public Health, given every third year for eminent services rendered to the public health, has been awarded this year to Surgeon-General Sir Alfred Keogh, G.C.B., Director-General A.M.S., and the gold medal for conspicuous services rendered to the cause of preventive medicine to Dr. E. W. Hope, M.O.H. for the city and port of Liverpool, and professor of public health in the university.

AT the meeting of the court of the Royal Victoria Infirmary, Newcastle-upon-Tyne, on June 28th, it was announced that on the occasion of his retiring from the office of honorary surgeon under the age limit, Colonel J. V. W. Rutherford had presented the institution with the sum of £1,000 to endow a bed in memory of his father, who had taken a deep and active interest in the infirmary when it was on the old site. Colonel Rutherford was at the same meeting appointed consulting surgeon to the infirmary.

AN American Association for the Control of Syphilis has been formed to disseminate knowledge of syphilis among medical men, medical institutions, boards of health, hospital boards, dispensary attendants, and boards and other organizations having the care and treatment of syphilis. It is hoped to collect standardized statistics from the various institutions now treating syphilis; to further the establishment of free clinics and dispensaries for the diagnosis and treatment of syphilis, and to encourage the more comprehensive teaching of syphilis in medical schools.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Antiology, Westrand London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisecra, Westrand London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

QUERIES.

T. W. A. asks for information as to the treatment of gastroptosis, especially in regard to diet, prognosis, value, and form of electric treatment, drugs, lavage, and the best fluid for use, and any references to literature dealing with the subject.

MEDICAL MANAGEMENT OF CHILDREN'S HOMES.

M.R.C.S. would be glad to know of any books bearing upon the medical management of children's cottage homes, orphan asylums, and such institutions.

* * We cannot hear of any work specifically on this subject, but the inquirer might find something serviceable in Dr. A. D. Edwards's article on the medical examination of children under the Poor Law and in orphanages, in Dr. Kelyack's *Medical Examination of Schools and Scholars* (Westminster: P. S. King, 1910.).

LETTERS, NOTES, ETC.

THE "MEDICAL DIRECTORY."

THE Editors of the *Medical Directory*, 7, Great Marlborough Street, London, W.) write: The annual circular asking for information for the *Medical Directory* for 1918, was posted to members of the profession on July 3rd. We are anxious that these forms be returned to us as promptly as possible. If in any cases the circular has not been received a duplicate will be sent on application. It is especially desirable that those practitioners whose addresses are included in the London postal district should return the new district numbers.

CINNAMON AS A PROPHYLACTIC IN MEASLES AND GERMAN MEASLES.

DR. J. R. S. ROBERTSON (Hayling Island) writes with reference to Dr. W. B. Drummond's note on this subject on June 9th to say that he has recently made use of the suggestion in a V.A. hospital of fifty beds established in that island. A patient who had been admitted some days previously developed the typical rash of German measles while mixing freely with the other men. He was isolated as far as it was possible to do so, and all the patients and nursing staff were put on two daily doses of pulv. cinnamomi, as much as would lie on a shilling. At the end of four weeks there was no other case of German measles.

ERRATUM.

IN the announcement last week of two medical calls to the Bar, the name of Major Hugh Neville Adam Taylor was incorrectly given as Major Hugh Neville Adam.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

MEDICAL AND SURGICAL NOTES FROM MESOPOTAMIA.

BY

G. GREY TURNER, MAJOR R.A.M.C.(T.).

PART I.

THE WEATHER.

I WENT out to Mesopotamia with a British general hospital and landed in Basra in the beginning of April, 1916, and I am now writing at the end of December, so that my experience is of the dry season and not of the rains. True, after I first arrived there were some thunderstorms, with just enough rain to introduce me to the universal, intolerably slippery mud of the winter, but from April 15th to the end of October one day succeeded another with unfailing blue sky, bright hot sun, and an average maximum temperature of just 100° F. Very rarely a cloud appeared, and now and again there were penetrating dust storms, though usually there was not even a breeze, for the Shamal (north-west wind) almost completely failed. October, November, and December may be looked upon as the autumn. During these months it was hot in the sun and a topee was necessary, but the early mornings and evenings were beautiful, and those who were first introduced to the climate at this time thought it wellnigh perfect. The nights were cool and sometimes very cold, and in December the temperature once dropped to 42° F. On November 5th we had our first shower since April, but there was no heavy rain until December 26th. The monotony of the summer weather was only relieved by the interest taken by some of us in the temperature. I kept records of the maximum and minimum for the whole of my stay, and the main facts of my observations are set out in the following table. My thermometer was of English make, but not registered at Kew, though, on comparing it with others, variation was negligible. I lived in an E.P.I.P. tent with a double roof and with either the sides down or all the doors open. The thermometer was hung about half-way up one of the tent poles, and though the conditions were not such as would be selected for permanent meteorological records, the temperatures shown are those in which one actually lived and are thus of especial interest.

Record of Temperatures in Mesopotamia during Nine Months of 1916.

Month and Number of Days on which Observations were made.	Highest Maximum.	Lowest Maximum.	Average Maximum.	Lowest Minimum.	Highest Minimum.	Average Minimum.
April ... 18 days ...	100	74	87	60	74	65
May ... 30 ..	118	92	102	67	80	75
June ... 27 ..	118	90	105	70	84	75
July ... 22 ..	122	101	112	74	86	79
August ... 17 ..	118	104	108	70	83	75
September, 29 ..	112	93	103	58	77	66
October, 30 ..	100	83	89	50	66	58
November, 30 ..	89	67	81	46	73	57
December, 24 ..	74	42	66	42	59	46

The range of temperature was often remarkable, and on September 13th was as much as 47°, that is, from a maximum of 108° F. to a minimum of 61° F. It is interesting to compare the temperatures in July with those recorded at home for that month. (The latter are observations made at Newton-on-the-Moor, Northumberland, and published in a local newspaper. I am informed that the summer of 1916 in England was unusually dull and cold.)

Temperatures in July, 1916.

	England (Northumberland).	Mesopotamia (Amara).
Average maximum ...	66° F.	112° F.
Average minimum ...	50.5° F.	79° F.
Highest maximum ...	79° F.	122° F.
Lowest minimum ...	42° F.	74° F.
Greatest range ...	29° C.	46° F.
Rainfall ...	3.72 inches	None

Unfortunately I was not able to compare systematically the wet and dry bulb temperatures, but on what I call a typical "Basra day" in December the record gave 82° F. for the dry bulb and 80° F. for the wet. This amount of saturation alone has been proved to raise the body temperature,¹ and this question of humidity had undoubtedly a great deal to do with the frequency with which heat exhaustion and heat-stroke occurred.

The continuity of the temperature throughout the twenty-four hours was extraordinary, and as the following records show, at all times of day and night it is very hot.

May 18th.			July 28th.		
A.M.		P.M.	A.M.		P.M.
6.30 ... 86° F.	1	114° F.	6.45 ... 86° F.	1.30 ... 113° F.	
7 ... 82°	1.30 ... 115°		8.15 ... 100°	3.30 ... 110°	
7.45 ... 86°	3.30 ... 110°		11.30 ... 114°	4 ... 108°	
11.30 ... 110°	5.30 ... 102°		12 noon ... 114°	4.45 ... 107°	
	6.20 ... 95°			9.15 ... 92°	
	7.45 ... 88°				
Maximum for 24 hours ... 115° F.			Maximum for 24 hours ... 114° F.		
Minimum for 24 hours ... 75° F.			Minimum for 24 hours ... 82° F.		

Paradoxical as it may seem, it is nevertheless a fact that the heat is not always worst when the temperature is highest, and the most trying time was undoubtedly the moist heat of Basra in May and June. During these months perspiration literally poured from one. It began with the exertion of drying after the morning bath and continued until tardy slumber temporarily buried in oblivion the discomforts of a wet pillow, for there was "no freshness in the dawn," and each succeeding day brought the same discomforts. The constant state of perspiration in which one lived was a great trial, and in spite of the heat I found it a comfort to stand in front of the open fire which we used for sterilizing our drinking water. I believe that this extraordinary perspiration is partly paralytic, but even so it is a wonderful example of the power of the sweat glands, and it would have been interesting to try and measure the amount of fluid lost in this way. As a result renal secretion was much diminished, and most people only urinated twice or thrice in the twenty-four hours.

This excessive loss of fluid may also have accounted for the low blood pressure which I found to prevail. In a small series of observations made on comparatively healthy men the average was only 87½ mm. of mercury, and in the case of an officer whose pressure in England was never less than 135 mm. of Hg the manometer never registered more than 120 mm. Quite apart from the serious effects of the heat it is generally depressant, and vitality and resistance are both at a low ebb.

The temperature was usually highest about 2 o'clock in the afternoon, and it was between then and 3 o'clock that cases of abnormal pyrexia occurred among the patients in the wards. In fact it was so common that medical officers got into the habit of visiting their wards about that time, and quite often some case of dangerous pyrexia was discovered. For those who were up and about the most trying time was in the evening from about 5.30 to 6.30, and it was then that one appreciated the benefit of a little alcohol.

Food is of immense importance, and the principal difficulty is to secure enough variety. For a time vegetables were very scarce, but hospitals will become more or less independent as more attention is paid to gardens. Some of the Indian hospitals at Amara grow enough vegetables very considerably to augment the resources of the commissariat. This is a very important matter, for scurvy has been rife among the native troops. The lack of local grown fruit is very disappointing, for one rather expected luxuries in the Garden of Eden; but perhaps it is as well, for all who have lived for any length of time in the East warn one against eating uncooked fruit, and the temptation to do so would be great. Raw fruit is very liable to set up diarrhoea, which is always dangerous, and there seems to be a definite relation between the consumption of raw melon and the onset of cholera. Where dangerous infective intestinal diseases are so common it is a good rule to eat only such food as has come off the fire.

The quantity of liquid one consumes is almost as interesting as the quality, and while at Basra I never drank less than a gallon a day. I am a great believer in hot water as a thirst quencher, and used often to drink as much as a pint once or twice in the course of the morning. One of the effects of the heat is to cause loss of weight, and it was surprising how the "large men" of our unit diminished in size, though we all suffered to some extent. Even the Indian troops felt the heat very much; at first this may seem strange, for in many parts of India the heat is as great and as trying as in Mesopotamia, but the conditions under which they live in their own country lessen the discomforts materially. Nearly all the troops in Mesopotamia lived under canvas, but buildings either of stone or brick or mud with few windows, and those properly shaded, are the only suitable dwellings. In fact, in the hottest weather even the natives dig big holes in the river banks resembling caves, into which they retire as a means of shelter from the sun. The superiority of buildings as a protection from the heat was well illustrated on a day in June when the temperature in my tent was 100° F., for in the ante-room of the operating theatre, which was a building with thick brick walls, verandah, and double roof, the thermometer only registered 87° F. Of course, the living arrangements were more or less improvised, and though the patients were housed in good huts the staff and personnel for the most part lived under canvas, and neither punkas nor electric fans were universal.

The question of exercise during the hot weather is interesting, and one certainly requires very much less than at home. At Basra I did a good deal of walking, and I think that on the whole I did myself harm. But it is quite possible to work on the hottest days, and I was accustomed to operate and to work in the wards or *post-mortem* room with a temperature of 110° to 120° F., and I am sure one feels the heat less when well employed. The way the cooks were able to work, in spite of the heat and exposure, was a constant source of astonishment to me. Of course abundance of sleep is essential, and the natives always rest from about 11 a.m. to 3 p.m. during the hottest part of the year. I found it difficult to sleep in the afternoon, but it is surprising how much refreshment can be secured by merely resting with nothing but a towel across the pelvis, and, if very hot, a wet cloth tied round the head. The mental attitude has much to do with the way people tolerate the climate, and those who suffered most, and sometimes seriously, were often of a nervous, irritable disposition, and all through the depressing weather men of the Mark Tapley stamp were an invaluable leaven in the unit. There are many physiological points of interest to be worked out, and any one condemned to spend a hot season in the country might devote his spare time to their solution. For instance, the trivial amount of haemorrhage following the extraction of teeth, etc., led me to believe that the blood coagulated more readily than at home, and a small series of observations in the estimation of the "blood coagulation time" confirmed my suspicions.

INSECTS.

Of all the minor troubles none are so distressing as the insect bites, and, owing to their liability to become infected, they often lead to grave disability extending into

weeks or months; men were often in and out of hospital all the summer for no other reason. In my own case some infected bites on one of my feet were two months in healing, though I was never off duty. The insects are legion, but of all the many varieties probably only a small proportion bite, for which we were devoutly thankful.

It was a great and pleasant surprise to me to find that the men were not infected with lice, for after what one heard of the conditions in France I expected this "minor horror" to be very troublesome. Of course my experience has been limited to the hot weather, and I am told that in the winter lice did flourish. In the hot season the men are very lightly clad and their clothes are perforce exposed to the very powerful rays of the sun, which we know is too much for these parasites. Is it not Shipley who records the experience of a private who told him, "We strips and we picks 'em off and we places 'em in the sun, and it kind o' breaks the little beggars' 'earts"? But all through the hot weather body lice were very common among the native troops, and this small matter leads me to remark that in many ways the native and British troops are not comparable, and generalizations applicable to both cannot be drawn from the observation of either. When as consulting surgeon I had opportunities of seeing numbers of natives the differences in their resistance, attitude to disease, incidence of certain disease, etc., struck me very much. Of course, these are matters which must be very well known to all medical officers who have worked in India, but to the new-comer they are a surprise.

In one of the camps in which I lived the flea was responsible for an immense amount of discomfort; one officer of my acquaintance caught no fewer than thirteen on or about his person before breakfast one morning! But, of all the minor horrors, fleas are the most amenable to treatment, and Keating's powder, properly used, is a specific. It should be dusted on the socks and in between the folds of the putties, when it will furnish almost absolute protection. I do not know when the flea season commences, but it usually comes to an end about the middle of June. In the spring of 1916 they were only an inconvenience, but since the appearance of plague at Basra they may prove a very real danger.

Sand-flies are fearfully troublesome in certain localities, and I have never been so miserable as when the victim of their attentions, for the loss of sleep which they entail tends to make one very depressed. If it is not possible to sleep away from where they abound, a good deal can be done to discourage their attentions by smearing the face, neck, and ears with eucalyptus vaseline, and by wearing socks on both feet and hands, taking great care to tuck the pyjamas into the top of the socks. A solution of lysol freely daubed on the exposed parts and sprinkled on bed and pillows also helps to ward them off, but I was never fortunate enough to discover a specific, though I tried all the plans recommended. Though their bites are exceedingly sharp, the irritation only lasts a very short time, but they may give rise to phlebotomus fever, from which we have nearly all suffered, an irritable temper during convalescence being pathognomonic.

Mosquito bites are serious because of the malarial parasite which they may convey, but the most uncomfortable bites are those of some insect which produces a swollen area that may remain irritable for days. They may be infected sand-flies or infected mosquitos or some entirely different variety, but whatever their identity their effects may be serious. In my own case these bites produced large oedematous areas, which were attended with recurrent irritation for as long as a week at a time. The irritation usually came on when the part was exposed to the air, and, in fact, the only real relief is to keep the part protected from exposure. It is almost impossible to prevent scratching, and this almost invariably breaks the skin and introduces sepsis. Frequently ulceration developed, and some cases were attended with cellulitis and lymphangitis. I have often seen men covered with these sores; they were very slow in healing. The minor sepsis met with in this country is of a very resistant sort, and the defences of the body are at a low ebb.

Every gradation in the effects of sepsis was represented, and the relation between infection and resistance is

sometimes so low that a general infection may occur. I saw fatal septicaemia arise as a complication of what was apparently but a trivial sore.

The patient, a big well-built man of 22, was admitted with cellulitis of the foot, which had followed ulceration produced by wearing his boots continuously in the trenches for a fortnight. From the time of admission he was very ill, and had a high temperature. In spite of free incisions the ankle-joint became infected, and after a rigor the leg was amputated. Though he improved a little as the result of the intravenous injection of eusol death occurred a week later.

A mild and chronic form of pyaemia is quite common. Abscesses at first develop in the course of the lymphatics running from the affected part, but later subcutaneous abscesses form in distant areas as the result of the blood infection. Such patients have long-continued pyrexia and get exceedingly thin, but ultimately recover as the infection becomes attenuated. Sometimes a blood infection persists, and I am sure that it was the cause of the various unexplained cases of spontaneous joint effusion met with. In all such cases there was some antecedent history of septic sores which had been long in healing. I used to think that there was no leishmaniasis in connexion with these bites, and though I never saw what might have been a Baghdad boil, many of the cases were exactly like the descriptions of oriental sores or veldt sores, and just before leaving Amara I saw cases in which the Leishman-Donovan body was found. They must be looked for in the softened foci before ulceration actually occurs, or the discharge must be washed away from the ulcers and material selected from beneath the overhanging edges, for secondary staphylococcal infection very soon occurs. Quite apart from the question of leishmaniasis there is nothing like taking these troubles seriously at the outset, and it often pays to take a man into hospital for what may look like a very trivial condition. After treating any cellulitis by fomentations, etc., I found that there was nothing better than a few applications of iodine to sterilize the surrounding skin, followed by a simple spirit dressing, great care being taken never to let the part remain uncovered. Granulating sores must be treated *secundum artem*. Doubtless many other plans of treatment will do equally well, but this I found to answer admirably.

There is a manifestation of minor sepsis that is characteristic and very troublesome. It begins as a pustule, usually on a finger. At first it looks most trivial, but within twenty-four hours it is surrounded by an area of induration, but without much pain, lymphangitis, or constitutional disturbance. After another twenty-four hours it either bursts or has to be incised, disclosing a large slough, which separates, leaving an equally large granulating area. The process often extends to the bone, and the amount of sloughing is out of all proportion to the severity of the initial lesion. It was very common on the fingers of nurses and ward orderlies. This type of sepsis ought to be very carefully worked out bacteriologically, but the laboratory accommodation has been in such demand for other and more important things that, so far, it has not been possible to deal with this interesting subject as it deserves.

The seasonal variation among the insects was very remarkable. This is very well understood in connexion with those which have been the object of close study, such as the mosquito, but it may also explain the incidence of other diseases that are not yet recognized as being insect-borne.

Of other types of vermin I have said nothing, for I have not seen the bites of scorpions or tarantulas. We had men bitten by jackals. Naturally jackals are shy creatures; when they run amok they are most probably hydrophobic, and those bitten by them had to be sent for treatment to the Pasteur Institute at Kasauli (India).

MALARIA.

The types of disease varied very much in the few months of our stay. At Basra we had a large amount of malaria, but it is always common there at certain seasons of the year, and the up-river natives speak of it as "Basra fever." Every precaution was taken to protect the men from this scourge, but in a district which is riddled with creeks, and which during certain seasons is inundated, the difficulties of the sanitarian are great, and the most impor-

tant prophylactic measures are personal. The men were furnished with mosquito nets, and the orders were that each should take 5 grains of quinine daily. Anybody who has used a net will know how difficult it is to be sure that it is always efficient, especially as it adds so much to the intolerable stuffiness of the nights, and many authorities express grave doubt as to the value of quinine as a prophylactic. If the latter is to have a fair chance it is essential that it should be taken in an assimilable form. I made some observations on various kinds of tablets, and found that a very popular variety did not even disintegrate in water after twenty-four hours, and that the addition of an amount of hydrochloric acid equal to that in the gastric juice, or of a "ration" of lime juice, made very little difference. Our O.C. then issued the quinine in solution, and although it was very nasty I think there was some evidence that it helped to diminish the incidence of malaria among our own staff. In all cases of pyrexia malaria must be first excluded, and in a busy hospital with between thirty and forty admissions a day this was a very big undertaking for the pathologist. Some of the cases of malaria were of a very severe type, and there were quite a number of the malignant and cerebral varieties. Though it is recognized as the most protean of diseases, its manifestations were a surprise to most of us. Gastric irritability with persistent vomiting was common, and such patients could not take quinine by the mouth. Many times the great value of intramuscular injection was demonstrated, and no case of tetanus occurred as a result. Fortunately tetanus is rare after wounds in Mesopotamia, and most medical officers had never seen a case, but as the ground over which we are now fighting has been fouled since the spring of 1916, the conditions may prove different. I always injected 15 grains of the acid hydrochloride into the vastus externus muscle, and never saw any ill effect, either local or general. The situation appears to me to be much better than either the deltoid or gluteal region, for there are no considerable vessels or nerves that might be injured. Many patients with the cerebral type of disease died in spite of treatment, and there is no doubt that many so-called cases of heat-stroke were of this nature. In some cases the pathologist was able to demonstrate the parasites in the cerebral vessels after death. Though it was common to find the spleen palpable, the "ague cake" was rarely met with, and is only to be expected in very chronic cases. In one man who died of malaria I found a large collection of blood in the peritoneum, due to spontaneous rupture of the moderately enlarged spleen.² We had many illustrations of the lighting up of a latent malaria as the result of some operative interference, and this possibility must always be borne in mind and provided for by the exhibition of quinine. After any operation an unexpected rise of temperature is an indication for a blood examination rather than a sign of alarm.

CHOLERA.

Cholera, fortunately, was only sporadic, and there have really not been many cases. Though it is often taught that it is entirely a water-borne disease, many men with tropical experience are inclined to suspect the common fly as one of the main factors in its spread, and, as with all these diseases, attach the greatest importance to carriers. The treatment of cholera by the transfusion of hypertonic saline was attended with considerable success. These patients are so denuded of body fluids that they are positively shrivelled up, and the immediate effect of supplying some pints of fluid to the tissues is very remarkable. I have often heard the method spoken of disdainfully, but I feel sure that the criticism is not fair, and if there has been a want of success it is probably because the careful directions of Leonard Rogers and his co-workers have not been carried out. As cholera is more or less endemic on the Tigris it is indeed remarkable that it did not occur in epidemic form when we consider the possibilities of infection and the ignorance of the soldier in matters sanitary. Frequently men filled their water bottles at the nearest creek rather than go a little further or wait a little longer for a purified supply. Even in hospital I intercepted a patient going to the creek in order to fill a feeding cup for one of his fellows. On another occasion an orderly of more than average intelligence was found carefully sterilizing a piece of ice by washing it in

permanganate solution before allowing it to melt in his drinking water! It is also very difficult to prevent men patronizing the native vendors of cold drinks, sweetmeats, and other commodities, which are all potential germ carriers.

It is difficult for any one at home to realize the amount of pollution to which the creeks of this country are subjected. They are at once the sole water supply and the main sewer. Every sort of abomination is thrown into them, and it is the commonest of sights to see offal floating on the surface. Our water was pumped from the creek near the hospital, was then sedimented and chlorinated in water carts, and was finally boiled. For the latter purpose two tanks were employed, and no water was used until it had boiled for half an hour. The result was a most beautiful water, the only difficulty being that it could not be easily cooled; but this was a very small price to pay for a pure supply. Later on this difficulty was got over by storing the boiled water in large chatties, which were covered; the demand was so great that the water was never there long enough to get contaminated. As showing the necessity of this careful sterilization, I may mention that within 25 yards of the place from where our supply was pumped there was a wooden bridge, and during the course of its repair a human corpse was found in a high state of decomposition.

ENTERIC GROUP.

There have been many cases belonging to the enteric group, mostly paratyphoid A or B. However mild a disease paratyphoid may have been in the Mediterranean war area it was often very severe in the cases that came under our care. There did not appear to be any pathognomonic features and the variations in type were extreme. Cases with otherwise unexplained pyrexia lasting more than five days very commonly turned out to be of this nature. It was the milder ones that gave rise to the problems in diagnosis, and undoubtedly a large part of our difficulty was due to the fact that the patients were commonly not seen until the disease was either well established or the patient convalescent, but sent on to us for some complication. Some of the few cases which did develop under observation had rather severe abdominal pain, and in one instance I opened the abdomen under the impression that I was dealing with pelvic appendicitis. Fortunately the course of the disease was not influenced unfavourably.

Perforation is not common in paratyphoid, and in the numerous *post-mortem* examinations which I made it was quite unusual to find ulceration. I have seen specimens illustrating perforation, and know that one or two cases occurred, but during my stay in Mesopotamia, when we had a total of many hundreds of cases, I did not see a single case. I was several times asked to see patients in whom this complication was diagnosed, and on two occasions I opened the abdomen in the confident expectation that it would be found. In one of these there was infarction of the spleen, with haemorrhage into the peritoneal cavity, and in the other acute cholecystitis. Others of the patients died, and at the *post-mortem* examination I found perforation of the ascending colon, with liver abscess, the result of dysentery; acute paralytic distension of the stomach and intestinal tract; and cholera. In other cases the easy recovery of the patient showed the diagnosis to be wrong. So closely were the symptoms of perforation simulated in some of these cases that I should hesitate to accept any figures dealing with this complication unless supported by operative or *post-mortem* findings.

SCURVY.

Although scurvy among the British troops in Mesopotamia is only very rarely sufficiently obvious for the patient to be sent to hospital with a diagnosis, it nevertheless occurs, and has proved of much diagnostic interest and of importance in treatment. The cases can be arranged in three very definite groups:

1. Those in which scurvy is the explanation of some otherwise obscure haemorrhage.
2. Those in which it explains the sluggish healing of some wound or ulcer.

3. Those that occur in the course of some other illness for which the patient has been fed on sterilized foods for long periods.

The last class are etiologically akin to the scurvy rickets of infants (Barlow's disease), but the origin of the other cases is more difficult to explain. Whereas among the Indian troops whole regiments have been affected to the extent of from 30 to 50 per cent. of their effectives, only sporadic cases have occurred among the British, and it is perhaps only because of their exceptional interest that they have come before my notice. I myself believe that it is not entirely dietetic, and that lack in variety of food and monotony of surroundings have much to do with its causation. The actual symptoms of scurvy are often preceded by great bodily weakness and lethargy, conditions usually diagnosed as "debility," but which may be an earlier stage of the same nutritional condition that may later develop into scurvy.

The following case is a typical illustration of the first group:

A gunner, aged 26, was admitted to Amara with a diagnosis of haematoma of the thigh. He stated that he had usually been a perfectly healthy man, but that for the last four years he had had a delicate stomach, and had not touched anything sweet; for this reason he had always avoided sugar, fruit, and vegetables. He arrived in Mesopotamia in January, and had been up the line ever since. He kept in good health, and never had to report sick, though he said that for some time his gums had been tender, and sometimes bled when he cleaned them. About August 21st he started on a long march, and on the third day noticed some stiffness behind the left knee, but he went on and finished with the column, arriving at the destination on the tenth day. Two days later he had to report sick, and was sent into hospital on account of the swelling behind the right knee. At first it was only swollen, but after about four days the skin became discoloured.

On admission he looked quite a healthy man, though a little thin and sallow. The haemorrhage was very obvious as seen from behind; from the front the calf was noticed to be swollen, and there was discoloration up the inner side of the leg and thigh. Posteriorly the whole affected area was black and blue, the discoloration being darker at the extremities of the haemorrhage. The calf was indurated and slightly painful. He walked with a limp, and kept the knee a little flexed. There was no effusion into the joint. Scurvy suggested itself as the explanation, and on looking for other signs slight swelling and blood discoloration were found in the palm of the right hand and the lower part of the forearm. There were no petechial haemorrhages or other signs on the surface of the body, but the gums were quite typical. The teeth were very good, especially the incisors, but the gums around the latter were swollen and spongy, and on the apex of each pyramid between the individual teeth there was a bright red cap of submucous haemorrhage, like a bright red granulation, which bled easily. On the left side of the upper jaw there was a septic stump, and this was surrounded by especially well-marked swollen spongy gum. On September 14th the patient went to a concert and sat for a couple of hours. When he got up he felt a stiffness behind the right knee, and on September 16th he drew my attention to a patch of subcutaneous haemorrhage about the size of the palm of the hand on the inner side of the lower part of the right thigh and also a well-marked superficial haemorrhage in the popliteal space and upper part of the leg. He was put upon an ordinary diet with vegetables and a mixture containing citric and tartaric acids with syrup of orange and infusion of calumba. He improved rapidly, and by September 25th the haemorrhages were fading and the gums were nearly all right; by the end of the month he was sufficiently well to be transferred to a convalescent dépôt.

As examples of the second group I may quote the following case:

A man, aged 23, had been in Mesopotamia since the beginning of January and had been up the line all the time. He had kept quite well until the end of July when he developed what looked like trivial sores on the right foot, but as they made little progress he was sent down and admitted to a base general hospital on August 19th. Both these ulcers were typically indolent; the few granulations present were flattened and unhealthy looking, and there were no signs of healing at the edges; the discharge was thin and blood stained, and there was staining of the tissues around. The appearance suggested to me a scorbutic tendency, but the only confirmatory sign was the condition of the gums. The mouth was clean and sweet, and the teeth very good, but on the apex of the pyramids between each of the incisor teeth there was a tiny red haemorrhagic spot and a similar red line along the edges of the gum surrounding the molar teeth. Under appropriate antiscorbutic treatment the ulcers soon took on a healthier appearance, though their ultimate recovery was longer delayed than I had expected.

Examples of scurvy coming on in the later stages of some chronic disease like typhoid or dysentery were quite common, and several developed in hospital.

I was asked to see a man in the dysentery ward on account of an effusion into the knee-joint. I found the patient bright and cheerful but exceedingly emaciated. The right knee was flexed and contained a good deal of fluid. It was neither painful nor tender, there was no temperature and no haemorrhagic staining. I could not discover the cause, and thought that it might be an example of so-called dysenteric arthritis. The joint very soon improved and the man began to get about again, but two weeks later he suddenly developed a large subcutaneous haemorrhage down the inner side of the leg and extending into the instep and sole of the foot.

Another man recovering from a bad attack of enteric fever and who had been on milk diet for several weeks rapidly developed a large haematoma on the buttock, the tissues all round were also infiltrated with blood, and there were petechial spots on the legs. I drew off 30 c.cm. of broken-down blood clot, and a few days later a similar amount of haemorrhagic pus was evacuated by incision.

When well marked the characteristic appearances of the gums affect the whole mouth, but when only slight they may have to be looked for on the inner aspect and especially around some septic tooth or stump. The petechiae are nearly always confined to the lower limbs and the front of the chest, though they may be found elsewhere. The large haemorrhages occur either subcutaneously or into the muscles. The former are most common behind the knee or on the inner side of the leg and extending into the instep and sole of the foot, but they may be found in the palm of the hand and over the middle of the sternum. The deep haemorrhages are also commonest at the back of the knee, deep in the popliteal space, down the front of the leg, among the muscles on the dorsum of the foot, and on the back of the forearms.

In addition to these large intramuscular haemorrhages, there may be small haemorrhages among the muscles of the thigh or buttock. Quite often they are multiple and not infrequently suppuration takes place.

ACUTE FEBRILE POLYNEURITIS.

BY

GORDON HOLMES, M.D., C.M.G.,

LIEUT.-COLONEL (TEMP.), R.A.M.C.,

CONSULTING NEUROLOGIST, BRITISH ARMIES IN FRANCE.

Most cases of polyneuritis which are met with in practice can easily be traced to intoxication by an organic or inorganic poison, or are complications of an infective illness, but the etiology of others is less certain or is unknown. Many of these have been called "rheumatic" or "influenzal" neuritis, or have been attributed simply to exposure to cold.

The cases with which we are concerned here are characterized by such a uniform and constant combination of symptoms that it is advisable to describe them as a type, though nothing is known of their actual cause. As their onset is usually acute and almost always associated with a rise of temperature, they may be provisionally included under Sir W. Osler's title, "acute febrile polyneuritis." Similar conditions have been described in other textbooks under this same title, or as "infectious polyneuritis."

Such cases have often been observed in irregular epidemic form, generally during the winter, but they also occur sporadically. Several came under my observation in London during one winter some years ago, and the course and the symptoms of those I have seen in France have been identical, or at least very similar, in all particulars. I have examined or have obtained notes on about twelve cases during the last winter. They have occurred among men from all parts of our front as well as from the lines of communication, and consequently they cannot be with any probability attributed to local conditions. The relatively small number that have come under observation suggests that there is no reason to suppose that the disease has been more common than it is in civil life, or that it is directly due to the conditions of life of our forces in France.

EARLY SYMPTOMS.

The onset of the illness is usually rapid. Almost all patients have stated that it began with a general malaise or with fever, at first without any definite local manifesta-

tions; several cases were in fact diagnosed at this stage as "pyrexia of unknown origin." One case developed a short time after an attack of relapsing trench fever, and another had had within the previous few weeks an attack of vomiting and diarrhoea. It has rarely been possible to ascertain the degree or the type of fever at the onset; in some patients the temperature did not exceed 100° F., but in others it rose to 102° to 103° F.

The next symptom was generally pains in the legs and in the lower part of the back, which usually set in on the second or third day and persisted. A day or so later, though occasionally even from the commencement, the patient found his legs weak or experienced difficulty in walking any distance. This paresis increased rapidly, and the arms became similarly but less severely affected. About the same time, too, the patient generally noticed that his face was "drawn" or "stiff," and several complained that even in this early stage their speech had become unnatural, or that they had some difficulty in swallowing.

SYMPTOMS OF THE ESTABLISHED DISEASE.

Most of the cases came under my observation when the disease was fully developed, and its clinical symptoms are then extremely characteristic. The lower limbs, which are equally affected, are flabby, toneless, and extensively paralysed, but the paralysis is rarely complete in all groups of muscles, and often all are in fact more or less uniformly affected. Neither now nor later is muscular atrophy a pronounced feature, and contractures did not develop in any case under my observation. The feet are dropped, the toes pointed, and occasionally no movement of either toes or ankles is possible. The movements at the knee-joints, and especially extension of the legs, are usually less severely affected, though they, too, may be paralysed in the severer cases. Even in these, however, the patient can with effort flex, extend, adduct, abduct, and rotate his thighs, though the movements are of small range and feeble.

The affection of the arms is usually less severe, and it is rare to find any movement completely paralysed, though the distal segments are usually very weak; as a rule, the feebleness is remarkably uniform throughout the limbs. The muscles of the trunk are much less seriously involved, though the intercostal and abdominal muscles are weaker than normal. In the two cases which died from pulmonary complications the paresis of the respiratory movements was probably a contributory factor to the fatal termination. I have not observed palsy of the diaphragm.

Thus far the motor disturbances correspond closely to that of any type of generalized peripheral neuritis, the only striking feature being the relative uniformity of the paresis and the fact that the distal muscles of the limbs may not be much more severely involved than the proximal groups. But when we examine the muscles innervated by the cranial nerves we find that certain of them are particularly severely involved. The face is invariably much affected from the early days of the illness; the facial folds disappear, the cheeks are flat and smooth, the forehead devoid of wrinkles, the lips slightly everted, and when the patient is asleep or dozing the eyes are incompletely covered by the lids. The face has consequently an expressionless appearance, which, if once seen, cannot be again mistaken. On further examination it is found that all groups of muscles supplied by the facial nerves are severely paralysed; the patient is unable to wrinkle his forehead, frown, close his eyes firmly, blow out his cheeks, or whistle. Articulation is slurred and indistinct owing to the palsy of the lips, fluids often dribble from the corners of his mouth if he attempts to drink, and he complains that during mastication the food frequently collects between his teeth and cheeks.

The tongue has not been affected in any case I have seen, nor is the palate often involved, though a few men complained of occasional regurgitation of fluids through the nose on drinking. On the other hand, almost all experienced more or less difficulty in swallowing solid food, and in one case this attained a severe degree. Phonation was unaffected, and there were no symptoms to suggest laryngeal palsy, though the larynx was not examined directly in any of the cases. The muscles of mastication were occasionally weak.

The pupils are equal and circular and their reactions are normal, but diplopia, due to ocular palsies, was present in three cases at least, in two of which an external rectus was almost completely paralysed.

The deep reflexes, the arm-jerks, as well as the knee and ankle jerks, are usually absent from an early stage of the illness, though in one case I was able to elicit a feeble response on tapping the patellar tendons when the legs were already parietic. The superficial abdominal and cremasteric reflexes, on the other hand, can usually be obtained, but the plantar reflexes are absent when the lower limbs are severely affected.

Sensory symptoms are less prominent than the motor disturbances. Some men complained of dull aching pains in the feet and legs, but these were usually troublesome only when the limbs were moved or handled. I have not seen any man who suffered with pains comparable to those of a moderate case of alcoholic neuritis. The muscles of the legs, and less frequently those of the arms, are often slightly tender to compression, and in several the sciatic nerve was also painful when pressed upon or stretched.

When the various forms of sensation are tested surprisingly little disturbance is usually found, especially in superficial sensibility. Even the lightest contacts can, as a rule, be recognized everywhere and correctly localized, though this form of sensibility is occasionally dull on the feet. The appreciation of temperature and of pinprick is also unaffected, but heavy pressure on the muscles and tendons generally gives an unnatural amount of pain. On the other hand, the proprioceptive forms of sensation are frequently disturbed; the patients are unable to recognize passive movement within the normal range, especially in the distal segments of the limbs, and they have not an accurate knowledge of their positions in space. Further, the vibrations of a heavy tuning-fork are not properly felt, particularly in the feet and legs.

A certain amount of hyperaesthesia to moving contacts is occasionally present, more especially in the legs; rubbing with a wisp of cotton-wool or with the finger-tips, as well as gentle scraping with the finger-nails or any sharp object, gives pain or more discomfort than normal.

Another interesting feature was the almost constant disturbance of the functions of the sphincters; the majority of the patients complained that they had had for some days more or less difficulty and delay in starting and completing micturition, though the use of a catheter was never necessary, and a few had occasional vesical incontinence. Temporary incontinence of faeces occurred in one man.

Vasomotor, trophic, and secretory disturbances are absent, or are at least not prominent.

The mental state of these patients was never affected, and showed no peculiarity; their general intelligence, memory, and power of attention remained intact.

In none of the cases in which it was examined did the urine contain albumin or sugar, nor did any other complication or disease that could be connected with this illness develop in any patient.

COURSE OF THE ILLNESS.

Two patients died, one from bronchitis the other from bronchopneumonia. Most of the others remained under observation for only short periods, though in a few instances the course of the illness could be followed for some weeks.

Most of the patients were first seen within a few days of its onset, but others only later. All the symptoms, and especially the paresis, reach their maximal development quickly, generally within a week or so, and in those who survived the progress of the illness was characterized by steady and rapid improvement which usually set in within two to three weeks of the onset. The pains and hyperaesthesia diminish quickly after the first fortnight or so, and somewhat later the power of the parietic muscles begins to return gradually, that of the arms usually before the legs. Some weakness of the facial muscles generally persists for a considerable time.

I have seen no patient in whom recovery had become complete, though one man whose legs had been much affected was able to stand alone about three or four weeks after the onset of the neuritis. Probably all do not recover so quickly, but in those who could be observed for some time the rapidity of the return of power in the affected muscles was striking.

The difficulty in swallowing and the sphincter troubles are among the first symptoms to disappear.

PATHOLOGY.

From two of the fatal cases I obtained for microscopical examination portions of the spinal cord and cerebral cortex, and from one of them pieces of one sciatic nerve and some lumbar and sacral roots.

The peripheral nerves and the spinal roots were fixed in osmic acid and were later carefully teased out. The sciatic nerve contained some fibres in the early stage of degeneration, their myelin sheaths being broken up into chains of spherical or oval globules, while the calibre of other fibres was irregular and their staining unequal; or there was a tendency to segmentation. The proportion of affected fibres was, however, small, and it was chiefly in the finer fibres that the change was most obvious. In the spinal roots, on the other hand, I could find no evidence of degeneration or other change.

The spinal cord and the cerebral cortex were stained only by Nissl's method. No evidence of inflammation, congestion, or infiltration by any type of cells could be found in either, or in the meninges covering them, but in the ventral horn cells alterations similar to those seen in other forms of peripheral neuritis were visible. Some cells were slightly swollen: there was a partial disintegration of the tigroid masses especially around their nuclei, and in a few instances the latter were swollen and more rarely eccentric in the cells. The only recognizable alteration in the cortex was a similar slight chromatolysis in some of the larger cells and especially in the Betz cells of the motor area.

Unavoidable circumstances made a more complete examination of the nervous system impossible, but these changes are sufficient to confirm the diagnosis of peripheral neuritis, and to exclude any other widespread affection of the nervous system.

In three cases the blood and cerebro-spinal fluid were examined, but no culture could be obtained from either, and the latter did not contain an excess of cells or present any other abnormal feature.

Finally, there was no evidence of previous abuse of alcohol, or of poisoning by any of the organic or metallic substances that commonly produce peripheral neuritis; nor did the disease develop after diphtheria, scarlet fever, or any other common infectious illness.

DIAGNOSIS.

The differential diagnosis of this condition does not present any great difficulties if its special clinical features are recognized. These are a rapidly developing and widespread flaccid motor paralysis, which involves to an exceptional degree the facial muscles, those concerned in deglutition, occasionally the ocular muscles, and the sphincters. Sensory disturbances, on the other hand, are relatively insignificant, and the amount of pain and paraesthesia is slight in relation to the severity of the motor affection.

The early date at which improvement sets in is another striking feature; as a rule, no recovery can be expected in alcoholic, lead, or arsenical neuritis of similar severity till a much later period.

This condition can easily be distinguished from the various forms of rapidly developing paralysis of spinal origin, though its confusion with acute ascending myelitis is possible. This, however, produces a true paraplegia with a more or less definite though variable upper level, severe disturbances of all forms of sensation in the legs and trunk, sphincter paralysis with retention of urine, and extensor plantar responses, even though the knee-jerks may be absent. Further, the cranial nerves are not involved, though visual disturbances, due to the presence of foci in the optic nerves or in the chiasma, are not uncommon.

From acute poliomyelitis it may be distinguished by the more rapid evolution and the more irregular distribution of the palsy, the frequent paralysis of the trunk muscles, and the usual absence of objective sensory symptoms in this disease.

Certain of the cases I have seen had been diagnosed as Landry's paralysis, and the separation of polyneuritis from this is less easy, owing chiefly to the vague and indefinite conception of this disease that characterizes its description in many textbooks; almost all forms of both peripheral

and spinal paralysis which show a tendency to an ascending course have been in fact included in Landry's paralysis, but it is now generally accepted that this term should be restricted to a condition which begins with a progressive paralysis of the lower limbs that rapidly ascends and involves the trunk muscles, later those of the arms, and as a rule leads to a fatal termination from respiratory palsy before the cranial nerves are affected. Objective sensory disturbances are also very slight or absent, and the sphincters are rarely involved.

The clinical symptoms of acute febrile polyneuritis are also sufficiently distinct to permit its differential diagnosis from other forms of peripheral neuritis, though none of the individual symptoms are peculiar to any one of them. The more usual causes of neuritis, namely, alcohol, lead, arsenic, and various organic poisons, as well as the recent occurrence of diphtheria, scarlet fever and of other infectious illnesses, should be in the first place excluded. From alcoholic neuritis it is distinguished by the relative uniformity of the paresis in the limbs, the early and marked involvement of the facial and deglutition muscles, the slight degree of the sensory loss and of pain, the absence of mental symptoms, and finally by the relatively early date at which recovery sets in and its favourable progress.

In neuritis due to lead the palsy almost always picks out at first certain groups of muscles, such as the extensors of the wrists, and if it becomes general it is usually associated with that group of cerebral symptoms which have been described as lead encephalopathy. Arsenical neuritis is easily recognizable by the prominence of gastrointestinal symptoms, pigmentation and trophic disturbances, serious sensory loss, early muscular atrophy, and its very slow convalescence; while beri-beri may be excluded by the absence of oedema, and vasomotor and cardiac symptoms.

TREATMENT.

The treatment in the present state of our knowledge can be only symptomatic. The patients should be kept warm and comfortable, the danger of respiratory complications should be guarded against, and care should be taken even from the beginning of the illness that the paralysed muscles are not unduly stretched. Certain of the cases seemed to benefit from diaphoresis and the employment of diuretics.

The Chadwick Lecture

ON

MENTAL HYGIENE AND SHELL SHOCK DURING AND AFTER THE WAR.

BY

F. W. MOTT, M.D., LL.D., F.R.S.,

MAJOR R.A.M.C.(T.F.).

MR. PRESIDENT, LADIES AND GENTLEMEN,—A new epoch in military and medical science has arisen in consequence of the employment of high explosives, combined with prolonged trench warfare, in this terrible war.

The term "shell shock" is applied to a group of varying signs and symptoms, indicative of loss of functions and disorder of functions of the central nervous system, arising from sudden or prolonged exposure to forces generated by high explosives. In a large number of cases, although exhibiting no visible injury, shell shock is accompanied by burial. Again, cerebral or spinal concussion may be caused by sand-bags, hurled from the parapet or parados of the trench, striking the individual on the head or spine. The soldier may be concussed by the roof or wall of the dug-out being blown in, or he may be driven violently against the wall of the trench or dug-out, or blown a long distance simply by the strength of the explosion.

It has been shown that the force generated by 17-inch shells is equal to 10,000 kilograms per square metre, or 10 tons to the square yard. This supports the contention that even death may occur as the result of aerial concussion, generated by high explosives, without visible injury. I think probably the cause of death in such a case would be sudden arrest of the vital centres. The stem of the

from oscillating by the anterior and posterior roots and the ligamentum dentatum. The cerebro-spinal fluid therefore acts as a water jacket to the spinal cord and water cushion to the base of the brain. A sudden shock of great intensity would be transmitted through this incompressible fluid, and seeing that it not only surrounds the central nervous system, but fills up the hollow spaces, ventricles, and central canal, and all the interstices of the nervous tissues, it follows that a shock of sufficient intensity communicated to the fluid would occasion commotion of the delicate colloidal structures of the living tissues of the brain and spinal cord. Such commotion would certainly lead to disordered function, and, if severe, to loss of function. The higher centres are the most likely to be affected; therefore consciousness, memory, sensory perception, and speech suffer. If the commotion is sufficient to arrest the functions of the vital centres in the medulla instant death would ensue, but it is difficult to determine in many cases whether the force was delivered by the hurling of a sand-bag against the head or spine or simply by aerial concussion in a confined space.

This leads me to call your attention to another important factor which may complicate the condition termed "shell shock." The soldier, while lying partially buried and unconscious, or at any rate helpless, may be exposed to various noxious gases, generated by shells or mines, especially carbon monoxide, or oxides of nitrogen, both of which are poisonous by reason of the deoxygenating effects upon the blood. Other poisonous gases from shells may produce most injurious and even fatal results; for example, cyanogen compounds, phosgene, which is chloride of carbonyl, etc. Both these gases are very deadly in their effects.

Malingering as shell shock is, I am informed by Captain William Brown, quite common at the front, and the detection of conscious fraud is not easy in many of these cases, owing to the fact that a functional neurosis due to a fixed idea or obsession, inhibiting will power, may be mistaken for malingering. Again, the notion of never recovering tends to become a fixed idea, and this fact is of considerable importance in respect to discharge from the army "permanently unfit," and the subsequent payment of pension and compensation. It is essential to be sure of your diagnosis that the disease is altogether functional, and being satisfied thereof, to avoid all forms of suggestion of non-recovery.

Mental and Bodily Condition at the Time of Receiving the Shock.

In considering the effects of shell shock on the nervous system, it is necessary to call attention to a complex of factors of extrinsic and intrinsic origin, apart altogether from the effects produced by direct material injury to the central nervous system by commotion and concussion. I will now consider the extrinsic conditions in modern trench warfare which lead in a neuro-potentially sound individual to nervous exhaustion, predisposing to shell shock. It must be obvious that through all the sensory avenues exciting and terrifying impressions are continually streaming to the perceptual centres in the brain, arousing the primitive emotions and passions, and their instinctive reactions. The whole nervous system, excited and dominated by feelings of anger, disgust, and especially fear, is in a condition of continuous tension; sleep, the sweet unconscious quiet of the mind, is impossible or unrefreshing, because broken or disturbed by terrifying dreams.

Living in trenches or dug-outs, exposed to wet, cold, and often (owing to shelling of the communication trenches) to hunger and thirst, dazed or almost stunned by the unceasing din of the guns, disgusted by foul stenches, by the rats and by insect tortures of flies, fleas, bugs, and lice, the minor horrors of war, when combined with frequent grim and gruesome spectacles of comrades suddenly struck down, mangled, wounded, or dead, the memories of which are constantly recurring and exciting a dread of impending death or of being blown up by a mine and buried alive, together constitute experiences so depressing to the vital resistance of the nervous system, that a time must come when even the strongest man will succumb, and a shell bursting near may produce a sudden loss of consciousness, not by concussion or commotion, but by acting as the

worn out by this stress of trench warfare and want of sleep.

In considering the effects of shell shock it is necessary to take into account the state of the nervous system of the individual at the time of the shock caused by the explosion. As I have indicated, a neuro-potentially sound soldier may, from the stress of prolonged trench warfare, acquire a neurasthenic condition, and it stands to reason that a soldier who is already neurasthenic from a previous head injury, or from acquirement of a disease prior to his being sent to the front, will not stand the strain so well as a neuro-potentially sound man.

Of even greater importance than the extrinsic conditions in the causation of military unfitness from exposure to shell fire are the intrinsic conditions, for if there is an inborn timorous or neurotic disposition, or an inborn or acquired neuropathic or psychopathic taint, causing a *locus minoris resistentiae* in the central nervous system, it necessarily follows that such a one will be unable to stand the terrifying effects of shell fire and the stress of trench warfare. A large number of the cases of shock which I see in hospital, and which especially require treatment by mental hygiene, are neuro-potentially unfit.

They come back after a short experience at the front, suffering with neurasthenia or hysteria, which persists for months and even a year or more; these are temperamentally unfit.

To take two concrete examples of the importance of the personal factor in the consideration of the causation of shell shock. A commercial traveller, with one year's training, three weeks in France, and three days in the trenches, was sent home suffering with shell shock; after six months in hospital, he is still tremulous and hardly able to stand or walk. He has done his best, but has cost as much as a cartload of shells. Compare the personality of this man with another, who was also admitted under my care suffering with spinal concussion, paralysed in all four extremities, with loss of control over his bladder and bowels. The history he gave was that he was in a dug-out, when an 8-in. shell burst 2 ft. behind the dug-out; he was partially buried, but did not lose consciousness; when he was rescued, he was found to be paralysed. Now this man shows none of the signs of shell shock. He has no terrifying dreams, and, although the concussion caused a haemorrhage into his spinal cord, followed by degeneration of the pyramidal tracts—namely, the paths of volitional impulses—nevertheless he is making a splendid recovery, and in two months is much less helpless than most of the severe functional cases of paraplegia, in which the paralysis of the legs is due to a fixed idea that they are unable to walk or stand. He appeared to be insusceptible to emotional shock.

As we know, one of the peculiarities of the functional neuroses—for example, hysteria—is not only the sudden manner in which an emotional shock may cause a loss of function, but likewise the sudden manner in which it may be unexpectedly restored by a stimulus of the most varied kind, provided there is an element of surprise—that is, his attention is for the moment taken off its guard. I am referring especially to hysterical mutism and aphonia. If the patient was neuro-potentially sound, he will recover as a rule from shell shock by rest of the mind and body under healthy conditions, without any special treatment. But the neurotic, the neuropathic, and the psychopathic individual, with an inborn or acquired *locus minoris resistentiae* in the central nervous system, is more difficult to treat successfully, for when an inborn or acquired predisposition to a neurosis or psychosis exists, functional disorders or disabilities of the nervous system tend to become organized by habit, and eventually firmly installed.

Before we consider the mental hygiene of shell shock it is necessary to point out the more important signs and symptoms, for although the general principles of treatment are the same, special functional disorders and disabilities necessitate special methods.

Effect of Shell Shock on Consciousness.

Most of the severe cases have suffered with loss of consciousness, or they have no recollection of what happened after the shell burst, and till they were at the clearing station or hospital; it does not follow that they were in a

cases have been recorded where, under hypnotic suggestion, they have been able to revive in consciousness some of the forgotten events. Often instead of complete unconsciousness loss of power of recollection seems to be the effect produced on consciousness by the shock.

Many cases have been admitted under my care at the Neurological Section of the 4th London, who had not yet recovered normal consciousness, and for some days were in a dazed, somnolent, or even semi-conscious condition. Usually these cases came at a time when large convoys were sent from the front owing to a recent engagement. The histories of cases sometimes showed that men absented themselves following shell shock, and, wandering away from the trenches, were found in a dazed condition, unable to account for their actions or to recollect how they came there. This condition is not unlike a fugue or automatic wandering of an epileptic; and indeed, in some of these cases there was a history of epilepsy or a predisposition to it, but in others no other cause was ascertainable than the conditions which induced shell shock.

A good many patients say that they can picture in their mind's eye the shell coming; they visualize the death and destruction caused, and they can revive in memory the sound of the explosion, but a blank of variable duration in their recollection of events follows. Many of these patients have not really suffered with either cerebral commotion or concussion, and in strict acceptance of the term are not true shell shock cases. Cases of severe concussion or commotion have not only an anterograde but also a retrograde amnesia, and these cases may sometimes show such a complete loss of memory of any event in their past life that they do not know their own name or where they live; in fact, their recollection is a blank, as if the commotion had obliterated the storehouse of the mind and its contents. In these cases it is quite probable there has been either an additional factor of concussion or burial with gassing.

The drowsy stupor which many of these patients suffer from may disappear gradually, or it may be associated with auditory or visual hallucinations of a terrifying nature, day dreams of the terrible experiences they have gone through. As the mind becomes more conscious of the external world, these day dreams are screened off, and, as a rule, are not able to pass the threshold of consciousness; but I have had cases where terrifying visual hallucinations have quite suddenly and unexpectedly induced all the external manifestations of fear—for example, profuse sweating, a wild terrified look and attempt to escape by flight, and when prevented from doing so, fear gave place to maniacal excitement and desperate struggling to escape. Some of the cases are obsessed with a terrifying experience. Now although, as a rule, in most cases these experiences do not come up into consciousness during the daytime when the mind is occupied in reacting to the constant perceptual chain of events, yet, if the mind is not diverted from introspection, they are always ready to obtrude themselves on consciousness, and this is clearly shown by the fact that one of the most constant, most serious and disturbing symptoms of shell shock is the terrifying dreams which are seldom, if ever, absent.

The Effects of Contemplative Fear.

Fear, in its depressing effects upon the mind and body, plays a very important part in the production of a hysteric or neurasthenic condition. Terror is contemplative fear; it is fear made more or less permanent by the imagination fixing in the memory past terrifying experiences, repressed in great measure by conscious activity of the mind during the waking state, but evident in dreams.

In addition to the revival of experiences of trench warfare—of hearing the shells burst and seeing the flash, of parapets being blown down, of being buried, of charging the enemy—soldiers often complain of a falling or sinking feeling.

I have had four or five cases of soldiers who in their sleep have gone through the pantomime of fighting with the bomb, with the bayonet, and with rifle. In consequence of the danger of injuring themselves in their unconscious but violent purposive motor activities, it sometimes became necessary to place them on a mattress in a padded room.

They are indicative of terror, and the signs and symptoms these patients suffer from are largely due to the continued effect of fear on consciousness. It is obvious that this fact is all-important to bear in mind when considering the mental hygiene of shell shock. When we come to consider the principal objective signs and subjective symptoms of shell shock, we shall see that they very largely correspond with those of paralytic fear. We speak of being paralysed by fear—of giving way of the knees, of trembling or quaking with fear, of being dumb with fear.

All these popular expressions regarding the influence of the emotion of fear on the human body are based upon actual experience, for paralysis, tremors, giving way of the legs, mutism, and cold, blue hands are among the most constant signs of soldiers suffering with "shell shock."

Influence of Fear on Phonation and Speech.

A frequent condition met with is aphonia and mutism, or inability to speak even in a whisper. This in no way differs from hysterical aphonia and mutism.

It is the conscious mind operating on the centres in the brain controlling phonation which causes this affection of speech, for mutes often shout in their sleep, and this may be the prelude to the recovery of their speech; one man recovered his speech on being told that he had been talking in his sleep by a comrade who slept in the next bed; he was so surprised that he said, "I don't believe it." Another man recovered his speech when pitched out of a punt on New Year's Eve; he had been mute for more than six months. This lad could not whistle, could not phonate in coughing, could not blow out a candle, yet he was heard to shout in his sleep. An x-ray examination of his chest showed that the diaphragm hardly moved even when he made a great effort; the fear effect on his conscious mind had inhibited the respiratory movements necessary for phonation, and the idea had become firmly installed in his mind. Breathing exercises to relax the contracted respiratory muscles may be usefully employed in some of these cases.

Suggestion and Hypnotism in Mutism.

Mutism is often accompanied by deafness; sometimes the patient recovers his speech and remains deaf. I have had a great number of cases of mutism and mutism with deafness, and in only one instance have I been unable by suggestion or other means to restore the function. A particularly intractable case came to the hospital, who had been deaf and dumb for nearly a year; I tried strong electric shocks, tuning-forks to the head, and sudden noises and hypnotism, without any result, but Dr. Yelland of the National Hospital, Queen Square, cured this man. I think the imposing array of electrical machines, coloured lights, and other strong suggestive influences, were partly instrumental in accomplishing what I had failed to do, but also I think the knowledge of success in other difficult cases attending Dr. Yelland's efforts played a very important part in curing by strong suggestion this apparently hopeless case.

When I have thought a patient was consciously prolonging his disability I have said to the sister aside, but loud enough for the patient to hear, "This man must be kept in bed on No. 1 diet, and when he can ask loud enough for you to hear he can have a bottle of stout and a mutton chop." I have had several get well the next day by this treatment.

Hysterical Sensory Dissociation.

The deafness may be partly functional, partly due to injury of the drum of the ear, or wax may be damped against the drum. Only about 17 per cent. of the cases of deafness are really due to, or partly due to, ear disease; the majority of the cases are purely functional, and due to dissociation of the sensory perceptive centres of hearing of the brain. They do not hear the tuning-fork, although they feel the vibration. There may be dizziness, but there are signs which clearly serve to differentiate this functional cortical brain deafness from the deafness due to damage of the organ of hearing and equilibrium, or the nervous structures in it.

Sometimes a man is blind, and an examination of the eyes shows that there is no injury or cause in them to account for the loss of sight. Vision may be lost suddenly, and restored suddenly; suggestion plays an all-important part not only in dissociating the visual perceptive structures in the brain from the nervous tracts which convey the light stimuli from the eyes, but in restoring the sight by reassociating them. Here I may say how important it is to ascertain how long a man has been in the front line in estimating how much of the functional disorder or disability is due to a pre-war neurotic condition.

Diagnosis of Functional Disease.

Often a slight injury or contusion to a limb will cause a functional paralysis of that limb, or of the arm and leg on that side; or a blow on the back will cause by suggestion a paralysis of both the lower limbs, so that the patient can neither stand nor walk.

There are certain signs known to the expert which enable one to determine whether the disease is functional or organic. These I will not discuss.

From what I have said you will understand that a great number of cases that are called shell shock are really hysteria or neurasthenia occurring in individuals predisposed to neurosis, and unable therefore to undergo the strain of modern trench warfare for any lengthened period of time. A number of conditions might induce the symptoms or signs of hysteria or neurasthenia in such individuals, particularly an emotional shock or intense fear. These cases of neurosis are really more difficult to deal with than those of neuro-potentially sound individuals who have suffered with the real shell shock, and where there has been either concussion with loss of consciousness, or cerebral commotion with loss of consciousness, or inhalation of poisonous gas.

Treatment of Shell Shock in the Early Stage.

I am informed by medical officers at the clearing stations that there is an increase of pressure of the cerebro-spinal fluid in shell shock cases, and that sometimes even it is blood stained or contains albumin; also, that relief of symptoms occurs by withdrawing fluid by lumbar puncture.

The treatment of cases of shell shock varies to some extent in different individuals, according to symptoms and signs, but there are some symptoms which are seldom absent in all true cases—namely, insomnia and terrifying dreams. I have found the continuous warm bath of great value in the treatment of these cases when they come over from France. The water in the bath is kept continuously at the temperature of the blood by a special mechanism of heat regulation; the patients are kept in the bath for a quarter to three-quarters of an hour, or even longer. The effect is most soothing on the nervous symptoms. These baths are extremely useful in cases of maniacal excitement. Often the bath, with a drink of warm milk at bedtime, suffices without hypnotics to produce sleep. But if hypnotics have to be given, the quantity required is less when combined with the baths. The next thing is to attend to the general bodily condition by nourishing, digestible, and easily assimilated food; and, lastly, very important is attention to the *primae viae*, by which autointoxication and cerebral congestion can be relieved. The severe headache from which these patients suffer requires relief by an icebag to the head, aspirin, phenacetin, and drugs which relieve neuralgic pains. After the patient has recovered from the more serious condition of shock and the mind is becoming more alert and interested in its surroundings, we have to consider how best to allay the symptoms which nearly all suffer from—namely, headaches, dizziness, tremors, feeble circulation, and exhaustion, readily brought on by mental or bodily effort. If the patient is sufficiently well to sit up, it is better that he should do so, at first for a few hours a day, if possible in the open air. To severe cases, the noise of gramophones, pianos, the click of billiard balls, and even musical instruments, excite and aggravate symptoms; quiet repose in single rooms, such as we have at the Maudsley Hospital, is undoubtedly a most important and necessary mode of treatment in the early stages of severe cases.

At the same time these patients should not be left alone; quiet and unstimulating diversion of the mind should be encouraged, to avoid introspection and dwelling

upon the terrible experiences they have gone through. These men are often too tired or unable to read, for want of concentration of attention, and may be amused by simple games, knitting or wool work, bead work, basket work, and net making.

Mental Hygiene in Later Stages.

As soon as they are better, patients are encouraged to play billiards, cards, and other games, in the winter time especially; also there are frequent concerts and popular lectures, all of which serve to divert the mind and produce an atmosphere of cure, which is very essential. Soldiers will put up with a good deal provided they have good and abundant food, and it is essential for recovery that there should be no grumbling. Grumbling and grouching are contagious, and it is always well to get rid of a soldier from a ward if he is exciting discontent in the others. Discipline is very essential; laxity of discipline, over-sympathy and attention by kind well-meaning ladies giving social tea-parties, drives, joy-rides, with the frequent exclamation of "poor dear," has done much to perpetuate functional neuroses in our soldiers. The too liberal gifts of cigarettes have produced a cigarette habit in officers and men which is highly detrimental in these cases of war neurosis, especially in cases of irritable dilated heart.

Again, in many functional paralyses, the idea of a permanent disability requiring pension for the rest of a man's life, may become a fixed idea, owing to wrong diagnosis, over-sympathy, and misdirected treatment. In many of these cases, as I have found, what is required is merely strong suggestion to the patient that there is nothing the matter with him except the idea that he is paralysed, which has become installed and firmly fixed in his mind by prolonged bed, daily massage and electricity, which has kept suggesting to him that there is an organic disease causing his complaint.

Some patients, owing to an injury by a fall caused by an exploding shell, have developed a functional paralysis on the side of the injury, either arm or leg, or one of these limbs. Supposing it is the arm that is so affected, I perform a number of associated movements of the two arms together—the healthy one and the paralysed—myself assisting the immobile arm, telling the patient at the same time to help me by thinking of the same movement. After a little while he may be doing the main part of the movement himself. In all these functional paralytic conditions of an hysterical nature a great tonic is to tell the patient that it is not at all likely that he will ever be sent back to active service, for he would be no use, and that what we want to do is to discharge him from the service in such a state that he will be fit to resume his previous occupation, or we can put him to some work useful to the State, whereby he will not be a burden to himself or the community. I am quite sure that if this method were adopted early, in a large number of cases known by an expert to be temperamentally unfit for military service, a great economic saving would be effected. Of course precautions would have to be taken against malingerers. I am sure that machines employed by doctors as a means of making the functional paralytics move their limbs are wrong in principle and in practice, and I entirely approve of the methods adopted by Colonel Deane at the Croydon Hospital of restoring function by natural methods, in which the mind is exercised.

Colonel Deane lays especial stress upon the value of associated movements, such as we get with the parallel bars, the climbing rope, skipping, football, Indian clubs, and the nautical wheel, and the ordinary apparatus of the old-fashioned gymnasium. My contention is that this apparatus can be applied to any man who is capable of any movement. The inestimable advantage is that his mind is projected into his paralysed limb, and all his sound limbs are being exercised at the same time. Constant change and adaptation is another advantage, especially when associated with mental occupation in the work. Diversion of the mind by useful occupation, both in the workshop and in the garden, have been most successful in restoring health and strength to these disabled men. This treatment I have been enabled to carry out through the generosity and kindly interest of Lady Henry Bentinck, who at her own expense has built in the grounds at the Maudsley Hospital a large workshop fitted with every appliance for carpentering, cabinet making, and

metal work, and with a first-rate instructor. There are patients, however, who cannot stand the noise of the hammering and tapping.

Agricultural Employment During and After the War.

I am convinced that occupation in the open air is a very beneficial mode of treatment of nervous cases in the convalescent stage. It does not, however, always seem to be popular with a certain type of case. In commencing the treatment of convalescents by manual labour, it is essential to regulate carefully the character of the labour and the number of hours per day, and the work should be so arranged and graduated as not to induce more than that gentle sense of fatigue that promotes appetite, interest, sleep, and the general sense of well-being. Each case, therefore, has to be inquired into and the individual encouraged to take interest. When a shell-shock case is discharged from the service who by upbringing or inclination has a desire to work on the land, means should be provided whereby he can do so. The money he earns for his labour should be supplemental to the pension money or gratuity.

TREATMENT OF CRANIAL INJURIES IN WAR.*

BY

CAPTAIN J. ANDERSON, R.A.M.C.

THE main object of this short paper is to urge the plea for early and complete operative interference in gunshot wounds of the skull.

By *early*, I mean the earliest possible moment after injury that the patient can be brought to an area where environment and staff are suitable for cranial surgery. Exigencies of military situation or type of campaign may affect this, but, as a rule, these areas are to be found in the casualty clearing station of to-day.

By *complete*, I mean operation on the lines suggested by Colonel Gray in his paper.¹ As I have no doubt you are all familiar with this, I will only touch later on certain points that have particularly appealed to me. I consider, however, that it is almost essential to actually see the method practised by one who is thoroughly familiar with the routine, in order to appreciate the finer points of technique.

Here I wish to emphasize that the operation must always be considered as one where a most careful and exact surgical toilet is to be observed if results are to be attended with success.

The findings of our French colleagues, as reported in the *Presse médicale*, February, 1915, was: "All wounds of the skull should be trephined at once, and that this is the operation of urgency *par excellence* in military surgery." Since then early interference appears to have increased in favour.

In earlier days I adopted the more conservative procedure of excision of scalp wound in minor cases, and evacuation to base for further interference if necessary. This is not good, because on arrival at base, if trephining had to be done, my excised wound had to be again excised to get rid of a possibly septic area. For the more severe cases I performed a complete operation, but left the wound open.

Those cases which I was able to trace compare unfavourably with our more recent results. I think, therefore, that the axiom "All or nothing" is a sound one to adopt in the majority of cases.

Since August, 1916, I have adopted the method as demonstrated to me by Colonel Gray. I had previously attempted this, but I found that I obtained more uniformly good results on observing one or two finer points wherein my technique failed. No other class of wound has given the same even and gratifying results.

I think *all* scalp wounds, perhaps with the exception of minute abrasions, ought to be excised. Suspicion of bone injury demands investigation. It is very frequently found, particularly in the frontal region, that what appears to be a simple symptomless scalp wound is one involving much brain tissue.

During an action many factors govern the question of issue. I feel certain, however, that no case of head injury

* Paper read at a meeting of medical officers of an army in the field.

should be allowed to pass on to the base without very careful examination. In certain cases it is perfectly obvious from the first that evacuation is out of the question. These include all cranial wounds with escape of brain tissue, and all cases with definite signs of cerebral compression, either from fractures or haemorrhage.

All doubtful cases also ought to be retained for immediate operation. These cases should be kept for at least five or six days after operation, if the situation permits.

Anaesthesia.

In only 3 per cent. of my cases (apart from those in which multiple wounds rendered general anaesthesia necessary) was the help of a general anaesthetic required, and then only to cope with restlessness or pain of injection if the preliminary opiate had not acted well. When general anaesthesia is required for other wounds infiltration of the scalp is still advisable. It affords the necessary haemostasis and freedom from immediate post-operative discomfort.

With simple local anaesthesia the operator can gauge much more accurately the general condition of his patient and the limits of legitimate surgery, while the post-operative shock becomes almost negligible. Of course, local anaesthesia requires some practice, and in nervous cases it may be unfair to persist with it alone, but one can usually desist from general anaesthesia after he is put well asleep.

The method I use is a primary injection of morphine or omuopon half an hour previous to operation; complete blocking of wound area with

Novocain	1 per cent.
Mag. sulph.	1 per cent.
Aqua, sterile or saline, add to	100 per cent.

Boil, and when cold add adrenalin, 15 minims, to each 30 c.cm.
Usually about 30 c.cm. are required for each operation.

It does not appear necessary to pay great attention to the preparation of an isotonic solution. I have seen no bad results from the use of solutions of widely differing tonicity.

Operation.

Our chief enemy in wounds of the head, as in other parts, is sepsis, and in order to defeat it we must completely remove its main attacking force before it has gained a secure footing, and at the same time place the defences at their best for resisting any further attack. To obtain this complete excision of the wound must be performed. The head is shaved; this is greatly facilitated if a hot anti-septic soap compress is applied to the head on admission. I have found a good depilatory of value in civil practice, and I think this might be extended to military spheres with advantage.

After disinfection by picric acid or iodine, the injured scalp is removed by an elliptical incision down to bone well clear of damaged tissue. The ends of the incision must be well freed, when it is easy to remove damaged tissue and pericranium with the handle of the scalpel or periosteum elevator.

One source of contamination has appealed to me frequently at this point of the operation—namely, weeping from soiled wound on to a clean area. I think this can be combated by the application of the actual cautery to the wound itself, sterilization and desiccation being thus procured.

Sufficient access to the wound of the bone can in almost every case be got through the elliptical incision. The turning down of flaps is practically never required for this purpose. They may, however, be employed with advantage: (a) in removing a foreign body from the brain through an unwounded area; (b) in dealing with an extensive meningeal haemorrhage; (c) in decompression operations.

One now proceeds to excise the septic bone area. This can be done either by making a very small trephine opening outside the soiled area and completing the excision with a skull-cutting forceps just wide of the soiled bone, or by the "nibbling" method, in which case it is advisable to frequently change the nibbling forceps for clean ones. The former is better technique but I have

bone. It is better not to trim the edges of the opening accurately.

If portions of the dura are destroyed and soiled, these are cut away.

One can now proceed as with a clean case.

I do not consider a head operation complete which does not deal with non-pulsating dura or brain tissue. Unless free pulsation is present one cannot hope for the best results. Remember that the dura is opened at operation only after the field is rendered aseptic by excision—usually easy in cases of non-opened dura.

It is desirable that a skiagram should be taken in all cases. One cannot tell whether foreign material has penetrated or not beyond easy reach of the *index* finger, which is practically the range of legitimate interference in the majority of cases. It is found that the brain does not suffer from careful exploration by the finger, if the hole in the dura and the deeper track permit of its introduction fairly easily. The exploration must be done without force and with extreme caution. It will be found that usually the intracerebral pressure is sufficient to evacuate the foreign elements and pulped brain by *vis a tergo*. The finger really coaxes them out. When the skiagram shows that the foreign body is lying just beyond reach of the finger, or if it is too firmly fixed for the brain to "vomit" it out, a forceps or scoop may be used to extract or loosen it. These instruments should be used only in extreme cases, as they are apt to cause more damage than the finger. If the track is too small to admit the finger, any attempt at exploration is contraindicated without previously locating the foreign body by the *x* rays.

In glancing bullet wounds and in fractures, where it is evident that a foreign body has not penetrated, the fragments of bone are practically never beyond easy reach of the finger. Such cases need not be *x*-rayed in a "push," as the skiagram will only be of academic interest.

It is well to drain all cases except the very simplest. In the majority of cases the drain should not extend beyond the dural opening. The smallest possible drain ought to be used. I prefer a perforated rubber glove finger with salt therein. If the wound in the brain shows a tendency to ooze blood, use a tube. If the brain is infected, drain direct to surface—if not, drain to one end of wound. If the track is grossly infected, a piece of folded rubber with salt therein, and possibly also a small rubber tube, should drain the brain to a "direct" opening. Immediately before introducing the drain, the length of the track should be ascertained by the finger. It is always shorter than the depth to which fragments have been driven.

I have found aeroplane dope varnish, with 1 per cent. picric acid, to be an excellent transparent dressing, used with gauze in the same way as mastisol.

Where many small wounds bespatter the head in the neighbourhood of a large one, and all are obviously septic, I think it wiser to salt-pack for twenty-four to thirty-six hours previous to operation.

In wounds of the large venous sinuses, the value of the "postage stamp" graft is marked. It is easy to apply and efficient. I favour a graft from some distant part, rather than from the neighbourhood of the wound.

Operative Findings.

Wounds of the head show a remarkable tendency to heal by first intention if gross sepsis is removed and pressure relieved.

Wounds of the head left open show a similar tendency to become secondarily infected. Healthy brain tissue with good blood supply can apparently deal with all minor sepsis. Such, no doubt, is present in many cases at the end of the operation; therefore, when in doubt, drain. An open wound often develops fungus cerebri, which is usually an omen of disaster and an associate of infection. I have yet to see marked hernia cerebri in a first intention wound.

In the great majority of cases the elliptical wounds resulting from excision can be closed, owing to the mobility of the scalp, if all layer sutures are used with superficial sutures between. It is well to work from each end in tying the sutures.

In cases where complete closure cannot be obtained by

The method I favour most is the extension of the original incision to form a large U or S flap.

FIG. 1.

FIG. 2.

FIGS. 1 AND 2.—To illustrate plastic operation for closure of an elliptical loss of tissue in the scalp. Fig. 1: First stage, showing line of incision for detachment of flap. Fig. 2: Operation concluded.

To close an elliptical loss of tissue in scalp by plastic method, the ends of the wounds may be sutured to reduce the amount of plastic necessary (Fig. 1).

An S incision is made as indicated by the dotted line (Fig. 1). The end A should extend well beyond a line drawn at right angles to the main axis of, and through the end of, the raw area. The scalp is undermined completely to any desired extent, as indicated by the shaded area. This is easily done by thrusting a curved blunt-pointed scissors, concavity towards the skull, between the aponeurosis and pericranium, opening the blades and withdrawing. Here and there it may be necessary to cut away resistant strands of tissue. Suture at *a-a'* to see how the flap comes. Sutures at the base of the flap should be inserted obliquely, as at *b-b'*, *c-c'*; when tied they help to remove tension. When fully sutured there should be little tension—if there is much, the scalp should be scarified repeatedly between the sutures, sufficiently to draw blood.

FIG. 3.—Diagram of plastic operation for triangular defect in the scalp.

the dura. Thus this method has an advantage over that of turning down a flap, and is no more elaborate. For a triangular defect, proceed as shown in Fig. 3.

After Treatment

think it helps to prevent hernia. Constipation is a feature of these cases. Early action of the bowels is always important. All head cases are given as a routine after operation, calomel gr. vj, followed by salines next morning. Urotropin gr. xx every four hours for thirty-six hours, then intermitted for twenty-four and later repeated, undoubtedly helps to render the cerebro-spinal fluid more capable of dealing with bacteria.

The drain is usually removed in twenty-four to forty-eight hours after operation.

Lumbar puncture ought to be resorted to *before* any marked signs of excessive cerebro-spinal pressure occur—for example, for persistent headache, focal spasms, or a tendency to hernia cerebri. These symptoms are frequently due to local interference with circulation. Removal of cerebro-spinal fluid seems to allow in most cases a rapid readjustment. This may be of importance in preventing "spreading oedema."

The amount removed varies from 10 to 30 c.cm. at a time, according to the amount of pressure. The wound, especially if open hernia cerebri is present, ought always to be observed during removal of fluid, which must be done slowly, in order to prevent breaking down of protective adhesions in the neighbourhood of the lesion.

EARLY TREATMENT OF GUNSHOT INJURIES OF THE SPINAL CORD.*

BY

TEMPORARY COLONEL H. M. W. GRAY, C.B., A.M.S.

To judge from the greater vulnerability of the spinal cord, its lesser capacity for recovery, and from the anatomical arrangement of the spinal canal, it might have been thought that the general desire to interfere in spinal injuries, and to prevent secondary complications, would have been as great as that shown with regard to cranial injuries, but this has not been the case. The technical difficulties of the classical operation of laminectomy, the loss of blood entailed by it occasionally under general anaesthesia, and the doubtful results of deferred operations, seem to be the chief factors in preventing patients, suitable for early operations, being treated on principles similar to those which govern our treatment of wounds in other parts of the body.

In these late cases the patients are usually in poor condition, suffering from pulmonary or urinary complications, and the parts are obscured by masses of fibrous tissue. But in early cases the presence of fractured laminae usually makes the operation a comparatively simple one; it is easy to perform under local anaesthesia, and the use of good adrenalin makes it practically bloodless. Pulmonary complications are not predisposed to, or influenced by, the anaesthetic. Operation in the early stages can, in fact, be done with extraordinarily little upset to the patient. Out of a large number I have never seen a death which could be said to have been hastened by it.

The fact that so many cases improve without operation, in spite of the abnormal conditions by which the cord is surrounded, would lead one to hope that they would improve more rapidly as well as to a greater extent, and that some cases otherwise permanently paraplegic might experience relief if they were submitted to early operation. The cord, to a greater extent than most parts of the brain, is deleteriously affected and retarded in recovery by pressure of fragments of bone, foreign bodies, and other debris. There seems reason to believe that it responds well to prompt removal of these unnatural conditions.

In a casualty clearing station, however, during an action, a hurried selection of cases for evacuation must be made. Under present conditions only those which are most favourable must be retained. In all cases which are sent off by ambulance train the urine should first be drawn off if retention be present.

Some general considerations in making the decision are here mentioned.

There are three types which arrive at a casualty clearing

station showing paraplegia—one in which the symptoms are due to local concussion, another in which the cord is organically severed, and a third in which paraplegia has developed since the injury. The paralyzing effects of local concussion are often very marked. This may be caused even by the flight of a missile close to but outside the spinal canal; for example, temporary paraplegia may follow the passage of a rifle bullet from side to side between the spinous processes. In such cases the paralysis usually begins to clear up within a few days.

If no sign of return of function occurs within nine or ten days, the question of operation for removal of blood clot or possible depressed bone occurs, but must be decided at the base. If, on the other hand, a rifle bullet causing a through and through wound of the trunk traverses the spinal canal, the cord is usually hopelessly pulped. An estimate should therefore be made of the probable track of the bullet, bearing in mind that the position of the patient during examination may not correspond to that in which he was hit.

It is obvious that cases of complete sudden paraplegia should not be kept in the casualty clearing station if they are otherwise fit to travel. If, however, the paralysis has developed since the man was wounded, it is probably due to pressure from blood clot (when it is not likely to be absolute), or to displacement of fragments of bone during movement. In both these cases early operation may be indicated, but in the latter only if *x* rays show a minor degree of displacement. If displacement is great the cord is probably pulped.

If conduction, either motor or sensory, is present in the affected part of the cord when the patient is admitted to the casualty clearing station, it is usually found that fragments of bone are pressing on the cord, or that the missile causing the injury is in close relationship to it, and will probably have carried in sepsis. There may or may not be partial division of the cord. A missile with momentum sufficient to carry it far past the cord usually produces complete early paraplegia, even although it may not cause complete section. If, then, *x* rays reveal fracture or the presence of a foreign body partly or wholly in the spinal canal, operation should be done at once, with the quadruple purpose of relieving pressure, cleansing the wound, restoring normal circulation as soon as possible, and, thus, of combating sepsis.

In some cases pain is so excessive and uncontrollable by other means, that, whatever the amount of paralysis, operation is imperative in order to relieve the pain.

Selection of Cases for Operation.

Roughly speaking, it may be said that operation is indicated or advisable at a casualty clearing station:

- (1) In the presence of incomplete paralysis of motion or sensation below the lesion, especially
- (2) if *x* rays show displaced fragments of bone or the presence of a piece of metal in or near the cord.
- (3) When the symptoms of paralysis have developed after the infliction of the injury, unless due to inflammation in cases which have been "lying out," when operation is practically hopeless.
- (4) When pain, due to pressure on nerve roots, is excessive and uncontrollable.
- (5) In very exceptional cases, when the character of the wound is such that sepsis, although not already evident, is likely to develop and cause rapid death.

In all other cases it is better, when feasible, that the patient should be evacuated without delay.

In cases which are retained for more than a few hours in a casualty clearing station, urotropine should be given as a "routine" in an attempt to prevent cystitis. Too great care cannot be exercised in performing catheterization.

Certain Operative Details.

1. Local anaesthesia, by infiltration down to and including the periosteum of the laminae and articular processes, is as effective as in a trephining operation, and even more easily carried out. The patient should receive such a preparatory dose of morphine or omnopon-scopolamine that he becomes drowsy. It is rarely necessary to use a small amount of chloroform at any stage of the operation, unless the track of the missile is followed into non-anaesthetized tissues. A few whiffs may be given if

the patient complains much of the pain of the injection, but the latter should be gone on with during the administration. Adrenalin renders the field practically bloodless.

2. If the wound is in or near the mid-line it should be carefully excised down to the bone, as in a trephining operation. Suture is usually not advisable. If the wound is well to one side, a fresh, free incision should be made in the mid-line. This is sutured at the end of the operation, while the track of the missile is cleaned up and used for drainage purposes. Carrel's method should be applied.

3. Set operations should be avoided. A typical laminectomy is rarely indicated. The laminae can usually be nibbled away, as is done in most cases of trephining for depressed gunshot fracture, until healthy dura is exposed all round the injured area. All obstruction to the easy removal of fragments should be removed before any attempt is made to lift them out. The greatest delicacy should be exercised, especially if movement of these fragments causes pain or twitching. One of the great advantages of local anaesthesia is that the patient is capable of feeling such pain. This fact may prevent further gross injury to the cord.

4. If the wound is not sutured, if the dura has been opened, Carrel's method of after-treatment, with the patient lying on one or other side, should be carried out. If the dura is unopened a gauze pack may be used.

It will be seen that the operation, in cases suitable for it, is on all fours with trephining the skull in gunshot injuries, both as regards technique and indications for dealing with dura, etc., except that in the one case we are in contact with inert and in the other with vital portions of the nervous mechanism.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

DERMATITIS FROM EXPLOSIVES USED IN AIR RAIDS.

DR. SEQUEIRA's record of cases in the JOURNAL of June 30th, p. 894, induces me to supplement his notes from similar cases that have passed through my hands during a recent air raid.

The men, all soldiers, were engaged in digging out bombs, and when so doing did not wear any protective coverings. The orange staining of the skin, of hands, feet, and face, came on the next day; the hands were principally affected, and these were very deeply stained; the vesicles appeared five or six days later.

The main symptom complained of was the intense itching and irritation; the hands, as in the case of the staining, were most affected in this way. In one case the man suffered considerable irritation of the testicles. The staining on the feet and face has now, five weeks after its first appearance, disappeared, but the hands, which were so deeply coloured, are now peeling; the flakes that are coming off are stained and thickened; the new skin underneath the flakes is tender and red. There have been no outstanding constitutional symptoms. All the men complained of nausea for a few days, and were until now unable to enjoy their food. The taste was altered; they compared this to the sensation which is noticed when chewing tobacco.

No local treatment has been of any avail.

Folkestone.

W. J. TYSON, M.D., F.R.C.P.

In the BRITISH MEDICAL JOURNAL of June 30th Dr. J. H. Sequeira refers to some cases of severe dermatitis due to contact with powder from bombs dropped in the air raid on London on Wednesday, June 13th. On the day on which these cases first appeared at the London Hospital—namely, on Tuesday, June 26th—there came also to the skin department at St. Bartholomew's Hospital twelve persons suffering from this complaint. All these patients had what might be described as severe pompholyx, and the only difference from the more ordinary cases of pompholyx was in the deep yellow staining of the skin of the palms and fingers and soles and toes. As in Dr. Sequeira's cases, the eruption first appeared on Friday evening or early on Saturday morning, nine days after the air raid. Among the patients were the mother and four

children in one family, two boys in another family, one of the hospital porters, and several isolated cases. All these patients had come into contact with the yellow powder which filled the houses and streets after the raid—the mother in scrubbing down the stairs, the children and others in walking or playing or searching for relics in the dust. The clearest evidence of the nine days' incubation period was in the case of the hospital porter, who came into contact with the powder only on one occasion—namely, when carrying in wounded victims on June 13th—and in that of another patient who on June 14th dipped his hands into a pail containing water into which part of an exploded bomb had been placed, and in whom the rash appeared during the night of Saturday, June 23rd.

The eruption reached its acme in from four to five days. There was no inflammatory redness, but only the clear "sago-grain" vesicles, characteristic of cheiropompholyx, which appeared deeply under the thick epidermis, rapidly enlarged, and ran together to form large blebs, in some instances as large as a hen's egg. These vesicles, large and small, covered the palmar surface and sides of the hands and fingers and the interdigital spaces in all cases, and in two-thirds of the cases similarly affected the soles and the toes. In some the backs of the hands and feet were swollen, but in no case was any other part of the skin involved.

In the course of a week most of the vesicles had dried, and the horny layer of the epidermis was beginning to separate and to leave a new, pink, healthy epidermis. All the patients suffered severe pain—so severe that they were kept awake at night by it. In none of the cases was there suppuration, and this perhaps may be attributed to the fact that they were instructed to soak the hands and feet for half an hour several times a day in hot water, a proceeding which also eased the pain. After the soaking, calamine lotion was mopped on.

These cases are interesting particularly on account of the incubation period, and also in that they perhaps throw some light upon the causation of what we have been accustomed to call "dysidrosis" or "cheiropompholyx," and to regard as due to irritation from toxic sweat, and in some way associated with debility from nervous or other influences. These cases suggest that the eruption known as pompholyx, dysidrosis, or cheiropompholyx, may in reality be due to some external poison which gets into the sweat pores and there produces irritation. They recall a remark made by Dr. J. J. Pringle in an article on cheiropompholyx in Allbutt and Rolleston's *System of Medicine*, that "the handling of irritating substances (for example, dyes) seems sometimes concerned in its production."

Physician for Diseases of the Skin,
St. Bartholomew's Hospital.

LAND SCURVY IN ENGLAND.

In the Poor Law Infirmary, Newcastle-upon-Tyne, during the last five years up to 1917, two cases of scurvy were treated, but during the last three months sixteen cases have been admitted.

Certain features have been noted which correspond with those observed in Glasgow (BRITISH MEDICAL JOURNAL, July 7th, p. 28). Thus all the cases have been men in the habit of frequenting lodging-houses. In my opinion the disease has been produced by the entire absence of potatoes from the diet. In ordinary times other vegetables are eaten to a very much smaller extent by the type of patient admitted to Poor Law infirmaries. With potatoes unobtainable, substitutes are found, usually in the form of bread, which does not possess antiscorbutic properties. In all the cases which have come under my view the usual story has been a diet of bread and tea, with perhaps some variety of tinned meat.

The public should be warned that foods containing antiscorbutic properties are necessary, and that such starchy substitutes as bread and rice are not sufficient.

The cases I have had under my care have been quite definite and easy of recognition, when the existence of such a disease as scurvy is remembered. The outstanding feature in all has been the presence of purpuric spots, chiefly confined to the extensor surfaces of the legs. Another constant feature has been haemorrhages round the knee and ankle and in some cases accumulation of fluid in these joints. When the ankle is involved all the

appearances of a sprain are presented. In addition haemorrhages have occurred in other situations and chiefly over subcutaneous bones (radius and tibia). The appearance is of an elongated, discoloured swelling. Several of the patients had ulcers on the legs; these were characteristic, with raised, thickened dark edges. They were also particularly indolent as far as healing was concerned. The condition of the gums varied, some of the cases having no involvement, others the soft, spongy gum, bleeding very readily. Lastly, there was constantly extreme anaemia, producing an earthy, dirty pallor of the face. The reason, in all the cases, for the patient seeking advice was the implication of the joints producing pain and stiffness.

The condition, fortunately, is very amenable to treatment, improvement following rapidly on a suitable diet with lemon juice and a mixture containing citrate of iron and quinine.

Poor Law Infirmary,
Newcastle-upon-Tyne.

Medical Superintendent.

Rebelsus.

SPIRITUALISM AND SANITY.

SIR OLIVER LODGE has become the chief exponent of what is commonly called spiritualism, and his advocacy has the more weight with the public because of his eminence as a scientific investigator and teacher. He published recently a book entitled *Raymond*, relating various experiences he and members of his family have had leading them to believe that they had held communication with the spirit of Sir Oliver's son killed in Flanders in 1915. Not many years ago Sir Oliver Lodge published a book entitled *The Survival of Man*, and Dr. CHARLES MERCIER has devoted a small volume to an examination of the doctrines and practices therein described.¹ Dr. Mercier addresses himself not to convinced spiritualists nor to those who have investigated the phenomena and found no reason to accept the interpretations put upon them, but to the "immense body of persons who have the subject more or less forced upon their attention by the strenuous propaganda of Sir Oliver Lodge," and "really desire to arrive at the truth." "I do not," Dr. Mercier says, "ask them to adopt my conclusions: I ask them to adopt my methods, which are the methods that Sir Oliver Lodge also recommends but does not follow."

The subject is one which must engage the attention of members of the medical profession because of its reaction on the mental stability of the very large number of persons who have lost near and dear relatives in the war. Dr. Mercier quotes at length the observations made by Dr. G. M. Robertson, Superintendent of the Royal Asylum, Morningside, in his annual report, to which attention was called in these columns some months ago (March 3rd, p. 302). Dr. Robertson strongly advises "those who may possibly inherit a latent tendency to nervous disorders to have nothing to do with practical inquiries of a spiritualistic nature" lest they should awaken a "dormant proclivity to hallucinations within their brains."

Dr. Mercier states that the subject of spiritualism never engaged his attention before, but he has evidently studied these two books very carefully, and his previous want of interest in the subject does not diminish his competence to form an opinion on spiritualism, for, having had occasion to read a great many books on the subject and many volumes of the *Proceedings of the Society for Psychical Research*, we are prepared to accept *Raymond* as a fair, if unusually voluminous, sample of the kind of story, the kind of evidence, and the kind of conclusions usually to be found in such publications.

After an opening chapter in which the subject to be considered is stated, Dr. Mercier seems to begin its consideration a long way off, but the reader will soon see that this is necessary in order to get a true perspective, and we do not counsel him to accept the author's licence to skip the second chapter, on the "grounds of belief." We do not propose to attempt to set out the contention of the book. To do so would not be fair either to reader or author; the argument is closely knit, and should be followed out as

¹ *Spiritualism and Sir Oliver Lodge*. By Charles A. Mercier, M.D., F.R.C.P., F.R.C.S. London: The Mental Culture Enterprise. 1917. (Cr. 8vo, pp. xx, 132. 4s. 6d. net.)

presented. Only this we will say, that a comparison of the evidence for spiritualism with the evidence for witchcraft is brilliantly worked out, and cannot be met by shoulder-shrugging silence—the parallel is too close, and where it ceases the weight of evidence is all for the truth of witchcraft. We wish Dr. Mercier's book a tithe of the circulation of Sir Oliver Lodge's, but hardly hope for it. Dispassionate analysis seldom commands the public attention easily won by passionate pleadings which jump with the desire of the many to believe; and here we would submit, with all the respect inspired by Dr. Mercier's sword play, that he has not taken the full force of Tertullian's famous *credo quia impossibile*, or at any rate has not fully brought it out, though it would have served the purpose. Tertullian was concerned to define the meaning of faith as distinguished from knowledge. His pagan antagonists reproached him with accepting things which were impossible—that is to say, contrary to the order of Nature. Tertullian replied: "Quite so: things it is possible to prove I know, but there are things not possible of proof which I believe by an act of faith." The point is surely fundamental to the discussion. If Sir Oliver Lodge were as frank as Tertullian, his attitude might be as incomprehensible to some of us as Tertullian's to the pagan, but it would command the respect due to ancient precedent.

SHELL SHOCK AND ITS LESSONS.

THE purpose of the small volume on shell shock,² by Professor ELLIOT SMITH, Dean of the Faculty of Medicine and Professor of Anatomy at Manchester, and Mr. T. H. PEAR, Lecturer in Experimental Psychology in the same university, is to present to the reader a simple non-technical exposition of the ascertained facts relating to the "shell shock" complex. At the same time it is a plea for the more rational treatment of what may be termed minor mental maladies.

There is hardly any department of medicine which has been so neglected in this country, not only from the clinical and therapeutic but also from the research standpoint, as that of psychopathy as apart from definite insanity. The writers do well, therefore, to direct attention at this time to our sins of omission in this regard. We provide hospitals which are second to none in the world for the treatment of lunacy, but we are lamentably lacking in our methods of studying the early deviations from mental health, and in our means, medical as well as legal, for handling them so that the disorder shall not become confirmed. The war has served to focus attention on a complex of symptoms due to the exhaustion of nervous energy, consequent on excessive psychic excitation acting in combination with various toxic and nutritional disturbances—factors which exercise a profound influence upon the endocrine system and through this system on the nervous tissues. The war has forced upon this country, as the authors point out, a rational and humane method of caring for and treating mental disorders amongst its soldiers. Believing, as they do, that the problems of shell shock are the every-day problems of "nervous breakdown," they have made their book a plea for the establishment of psychiatry clinics, a plea for research in connexion with mental derangements, a plea for the education of the mass of the profession in the means of dealing with such derangements in their earliest stages, and a plea for the removal of the stigma which attaches in this country to mental disorder however transitory. It is an object with which we are in the fullest sympathy.

The authors advocate a therapy in these nerve-shattered cases which is at once sympathetic and humane, based on ascertained facts and on sound common sense. They have from time to time in the course of their argument had occasion to refer to the backward place amongst the nations which Britain occupies in regard to these cases. It is painful reading to find that a nation so humane as the British should be so surpassed in any regard by a nation which has proved itself so inhuman as Germany. The authors have used a sharp spur, but if it serves "to prick the sides of our intent," as we hope it

may, we will forgive its sharpness. The book is one which will be read with interest and profit by all those who are interested in the progress of scientific medicine.

NOTES ON BOOKS.

DR. ALEX HILL contributes a little volume on *Food*³ to a series of popular Manuals of Health, of which Professor Barclay-Smith is the general editor. The author shows that he has not lost his knack of imparting and expounding the broad facts of physiology in straightforward, entertaining language. His aim is to set forth the fundamental principles of dietetics in simple terms; to show why food is needed, how much, and of what kinds. At the present time, when the general public can scarcely keep from thinking of food, Dr. Hill's little treatise on the chemistry of foodstuffs and the physiology of digestion should be of much value.

Professor H. GOUGEROT of Paris has written an excellent practical manual of diseases of the skin⁴ that should be of great service to practitioners of medicine and specialists in cutaneous disease alike. In the first part of the book a general account is given of the whole subject. The dermatologist's general objects and method of attack are detailed, and the data on which he must form a diagnosis and a prognosis, and the outlines and details of treatment are set out. The second part occupies four-fifths of the text, and is divided into twenty-three chapters, each devoted to one clinical or pathological morbid entity; thus the first five chapters are given to dermatoses that are irritative, non-irritative, bulbous, pruriginous, or associated with generalized erythema and desquamation. The last chapter of all deals with "unaesthetic dermatoses"—alopecia, hypertrichosis, and canities. Professor Gougerot's descriptions of the various dermatoses or skin diseases are excellently written, brief and to the point. Most of his attention, however, is given to treatment, and here he provides an abundance of detail based on his own practice in his clinics at the Saint-Louis Hospital in Paris. The illustrations are numerous, and for the most part both photographs and three colour autochromes are first-rate, a real help to the searcher after knowledge. There is a fairly good general index and also an index to the illustrations. The book is well printed, and gives good value for its cost.

DR. WILSON'S *Students' Textbook of Hygiene*⁵ is based on a course of lectures given by the author at Queen's University, Belfast, and is designed to meet the requirements of medical students, sanitary inspectors, health visitors, and others who are interested in public health. It gives a clear account of the principles of the science and of their practical applications so far as the moderate scope of the book allows. There are twenty chapters in the text, and these cover the ground in a highly adequate manner. Dr. Wilson gives a very lucid exposition of the many subjects with which the expert in public health is expected to be familiar, and shows no little skill in the selection of the matter he inserts.

In the fourth edition of his useful *Handbook of Midwifery for Midwives, Maternity Nurses, and Obstetric Dressers*,⁶ Dr. COMYNS BERKELEY has taken into consideration the raising of the standard of training by the Midwives Board. Whilst revising the work, and rearranging certain parts, he has widened its scope, and treated some subjects more fully than before. At the request of trained midwives in remote districts he has also included an outline of the treatment that a medical practitioner might be expected to give if his help were available. In its present form this handbook will, no doubt, continue to prove of much value to those for whom it is intended.

THE MESOPOTAMIA COMMISSION.

[Third Notice.]

THE GOOD WORK OF THE EXECUTIVE MEDICAL
OFFICERS.

IN Part XI of its report, entitled "Causes contributing to the errors of judgement and shortcomings of responsible authorities," the Parliamentary Mesopotamia Commission says that "in the story of the military successes and reverses of this campaign there constantly crops up, almost from the day of the landing of the force, evidence of shortage of transport of all kinds, of the antiquated equipment of the troops, of grave deficiencies in medical personnel and material, occasional shortage of rations at the front, and a great, if not total, lack of comforts."

The Force "Ill Found."

The force from the first was "ill found" to meet the privations and hardships inseparable from campaigning in Mesopotamia, and as its numbers increased bad went to worse. The Indian authorized scale of medical personnel was calculated for the needs of frontier warfare, where casualties were not likely to be large and the resources of India were close behind. When the force was increased to two divisions, plus a cavalry brigade, the medical establishment was, save for the addition of seven sections of a field ambulance, that which had been thought necessary for one division only. The Parliamentary Commission states further that the organization orders of the Mesopotamian force contemplated a lower establishment than is laid down for a frontier campaign, and that the actual amount of medical personnel in Mesopotamia was during long periods far below even this meagre scale.

*Advance with Inadequate Organization and Medical
Complements.*

Under peremptory orders to advance, General Aylmer commenced the operations for the relief of Kut when "his columns were inadequately organized as regards transport, staff, and, above all, when the medical complements were quite insufficient." (X, 29.) It appears that the original organization of the force did not include any wheeled transport for the sick and wounded; a few motors were used in the Ahwaz operations in April and May, 1915, and again at Ctesiphon, and, later on, ambulance wagons of the English pattern. Throughout the campaign, however, the usual form of ambulance transport was the army transport cart, a small springless cart of wood and iron, drawn by mules or ponies, and ordinarily employed for the carriage of supplies. The original orders of the force allotted an additional number of riding mules, but these seem to have proved unsatisfactory.

The Vincent-Bingley Commission considered the supply of surgical and medical stores and appliances to have been unsatisfactory up to March, 1916, and pointed out, first, that the system of supply laid down in the *Medical Manual (War) India* was ill adapted to meet the demands of a large force operating overseas 1,600 miles from India; and, secondly, that, owing to lack of river transport, there was such delay and uncertainty in the delivery of these supplies that medical officers were frequently hampered in their work. The Parliamentary Commission had evidence that there was a shortage of drugs, including emetine and quinine, but adds that it is convinced that there was never any general shortage of drugs, dressings, etc., at Basra, though these and similar medical necessities were on many occasions either in insufficient quantities or altogether lacking at the front. As a matter of fact, we believe that neither sodium sulphate nor emetine is on the list of drugs to be supplied to British and Indian hospitals fitted out in India. There was also a shortage or absence of ice above Basra, and the arrangements for obtaining potable water were defective or absent. There was a lack of sweepers for sanitary work, and at one time an absence of any suitable machinery for disinfecting clothing and other articles. (X, 14-19.)

Work of Executive Medical Officers.

These extracts and abstracts may serve to give some idea of the disheartening conditions under which the

executive officers, those actually dealing with the wounded on the battlefield, on their way down to Amara and in the hospitals there, had to work. The Parliamentary Commission speaks in several places of the excellent work done by the executive officers on the spot. (X, 105.)

"We believe," the Commissioners say, "that with the means at their disposal, and within the limits of their powers, the executive medical officers have unfailingly spent themselves in alleviation of the suffering of their patients, and there have been but few isolated exceptions to this praiseworthy rule. When the disaster of Ctesiphon was upon him Surgeon-General Hathaway, whose administrative capacity has been so seriously called in question by ourselves and the Vincent-Bingley Commission, took off his coat and worked strenuously at embarking the wounded. The trouble has been throughout failure to foresee rather than failure to mitigate disaster." Again, the Vincent-Bingley Commission, speaking of the fighting in January, 1916, say, "evidence before us abundantly proves that, generally speaking, the energy, kindness, and industry of the executive medical officers . . . was beyond all praise." The Parliamentary Commission endorses this encomium, and extends it to the whole campaign.

Major Carter's Reports.

It must be remembered that it was an executive officer of the Indian Medical Service, Major Carter, then in medical charge of the hospital ship *Varela*, working between Basra and Bombay, who, taking his courage in both hands, forced attention to the condition under which the wounded were coming down. In a report made on the arrival of the ship at Bombay (December 14th) to Surgeon-General MacNeece, then D.M.S. India, Major Carter gave an account of the deplorable condition of the wounded brought down by the *Medjidieh* and other boats, and went on to speak of the extraordinarily difficult position in which the medical personnel of the force had been placed. On the *Medjidieh*, a small river steamer, it had been necessary to crowd over 600 sick and wounded from November 24th—that is, immediately after the battle of Ctesiphon—to the evening of December 6th; the equipment of the field hospitals had to be abandoned to the enemy, and there was practically nothing left with which to dress wounds or treat medical cases. The Parliamentary Commission admits that the "successful evacuation of the wounded in the face of a superior and pursuing enemy was a fine military performance" (X, 59), and Major Carter states that "the men were loud in their praise of the devotion to duty shown by many of the medical officers under heavy fire, both in the field and at the point of attack on the Tigris. There is but little chance of recovery for men with severe gunshot fractures, who lie on the bare decks of boats and barges for thirteen days amid septic discharges, diarrhoea, and dysentery, swept at night by a wind that dropped nearly to zero, without any protection against the cold save their clothes and country blankets, which in the cases of total cripples were sodden with their own discharges and dejecta. I write this to protect from hostile criticism by the laity the members of the medical services, who in these primitive boats and cattle barges have struggled for thirteen days against the difficulties of a task that is happily exceptional in the war history of our Imperial forces. There is no shadow of doubt that the medical staff who accompanied these sick and wounded from Ctesiphon did all that lay in their power to help and tend their patients, but it was attempting to make bricks without straw." (X, 89.)

This report brought Surgeon-General MacNeece to Bombay on December 15th, who immediately wrote to the chief of the general staff, India, stating that "many of the sick, British and Indian, particularly the latter, were brought on board in a deplorable condition. . . . Between Kut and Amara the steamers and barges were stopped by Arabs, and had to go back three times. Barges and steamers were crowded, sanitary measures were deficient or wanting, and the men, particularly Indians, lay on the deck suffering from dysentery, passing their motions under them, and getting large bedsores. The whole business is bad. The medical authorities were only given sufficient steamers and barges to turn into hospital ships for 500 casualties (so I am informed); then, when the crash came, over 4,000 had to be got down any way." (X, 90.)

Colonel Hehir's Work.

The position of Colonel Hehir, who was the principal medical officer of the original force, is somewhat peculiar. The Commission recognizes that he showed watchfulness and foresight, that he called attention to the crying need for a proper water supply at Basra, that he took measures to cope with a possible outbreak of malaria, and warned the Indian Government against the danger of scurvy arising from the deficient ration of the Indian troops, and that he asked for and obtained antityphoid and small-pox vaccine and antitetanus serum. Of his medical dispositions at Ctesiphon it is said that, having regard to the inadequate means at his disposal, they were not open to serious criticism. The reproach against him is that his very success in "making do" with the inadequate means at his disposal in personnel and material was really a fault, because it blinded himself and others to the fact that the margin of safety had been reached, if not actually overstepped, and that a reverse in the field or a great increase in sickness must lead to a breakdown.

HEALTH OF MUNITION WORKERS.

(Continued from p. 16.)

THE first part of this article, which was published on July 7th, p. 13, gave some account of the foundation and activities of the Ministry of Munitions, and of the inquiries of the Health of Munition Workers Committee into hours of work, industrial fatigue, and the work of women and young persons. The present section deals mainly with incentives to work, diet, and canteens.

INCENTIVES TO WORK.

The inclination to work rather than to idle, though it varies in different individuals, is a physiological phenomenon as important as the desire for rest which at periodic intervals follows work. The ordered routine of a modern factory is a direct stimulus to the daily rhythm of activity and rest—the better the organization and hygienic environment the greater the activity, the worse the organization and environment the greater the need for rest.

Time and Piece Rates.

Certain kinds of work, generally either the most highly skilled or the least, can only be paid for by time. With the present shortage of labour the worker has little reason to fear dismissal; there is no inducement to special endeavour except that supplied by patriotism and pleasure and pride in work for its own sake. Good time-keeping can be encouraged by bonus or fines, but does not always mean good work. The good results that have been attained with payment by time indicate that, given suitable environment, the inclination to work is a deep-seated physiological phenomenon, and it is questionable whether in the end the best results may not be obtainable by trusting to the good faith of both employers and workers. The desire to bring direct stimulus to bear on the natural inclination to work has led to the introduction of payment for work done and at piece rates. The manufacture of munitions, so largely a repetition of minutely-subdivided processes, lends itself particularly to this form of payment. That well-arranged piece rates may act to increase the rate of performance of monotonous repetitive processes is shown by statistics as to seventeen girls engaged in drilling fuses. Two consecutive weeks, the first on time and the second on piece work, were compared, and it was found that the output in the second week was 24 per cent. higher.

The system of piece rates adopted by the employer must be carefully explained to the operatives. In one department of a great munition works the foreman, who had failed to make the system of payment intelligible to the girls, set a standard, and it was found that the output remained at this dead level, and this fact, combined with the record of the use of electric power, showed that the workers were going easy. At the same time other girls, working on processes for which no standard had been set, were increasing the output. The Factory Act, 1901 (Section 116), directs that an explanation of the system of payment shall be given in writing, and it is important that this regulation should be carried out, so that the

employed may be able to estimate their exact earnings correctly.

In some circumstances the lack of desire to earn more than the minimum may lead to bad time-keeping or slack work. This may happen with men of an inferior type, who, in normal times, would not be employed in such work at all. It may happen also with boys, who, however slack they may be in work or attendance, are confident that they will, on pay day, receive more than they want to meet their requirements. These classes do not know how to spend the money they earn, but a comparable effect may be produced by lack of opportunity to spend; for example, so much overtime may be worked that there is no Saturday afternoon holiday, or the neighbourhood may provide no opportunity either for recreation or for increasing the comfort of the home. That the environment of a factory has a great effect is shown by the fact that where hygienic conditions are good, transit easy, welfare work properly carried out, and open-air recreation obtainable, the work and output are better.

Piece rates may cause wastage of workers through fatigue due to over-speeding of production. Dr. Vernon found in the case of lathe operators that though the strongest women available were picked out for the work, many of them could not stand it for more than a few weeks. Adequate records were obtained. Of 95 operatives, 22 gave up after four weeks or less and 11 more after ten weeks or less; but the cause of their retirement was not ascertained.

In a munition factory employing 7,000 to 8,000 males under 21, 25 per cent. of the total disappeared every three months, a loss which must partly be attributed to over-fatigue. Out of 287 girls at work in another factory, 30 had disappeared after eleven weeks; they were all strict piece-workers who had had enough experience to attain the normal level of productive power.

Such figures indicate a serious and undue wastage of skilled work, and the matter is now under investigation.

Rest Pauses.

The natural inclination to work is followed by a desire for rest, and physiological needs impel the workers to regulate their method of working. For example, a group working from 6 a.m. to 6 p.m. were engaged in filling presses, work entailing a fair amount of physical labour. During the thirty-five minutes for which pressure was being applied other presses were filled. It was found that instead of taking the full thirty-five minutes to do this the workers preferred to fill the presses in twenty-five minutes and then rest ten.

It has been ascertained that short rest pauses do not decrease the rapidity of work in munition factories. Proper rest pauses will prevent monotony, and the prospect of a rest and change to follow acts as an incentive to the completion of each stage of the work. The more arduous the processes the longer should be the rest pauses.

The value of well-planned rests in long-sustained athletic efforts is well recognized, and another lesson can be learnt from the trainers of athletes. They coach their pupils in the way to use their muscles with the greatest economy and efficiency. A worker should be induced to seek information as to his faults from a trained teacher so as to get out of bad habits unconsciously developed; such teachers would be able to give useful advice to the management as to the most suitable speed for running machinery, and as to the best moment to choose for rest pauses.

Other Incentives.

One of the greatest causes of dissatisfaction among average factory workers is the terrible monotony of the work. Employers and managers act wisely when they explain the character of the work and the part it plays in the world's economy. In one large munition factory where lectures with cinematograph illustrations, showing the evolution of the work and its use at the front and how the workers are helping to win the war, are given two or three times a week, not only has an increased output resulted, but only one overseer is required in place of the dozen or more that would be required for the same number of workers in a factory where such incentive is absent. Competitions between factories, with a trophy or money prize, act as incentives to increase output. Day by day the scores are marked up until the month's total in

each factory completes the competition. Further, just as the soldier is rewarded for good work so should honours be bestowed on munition workers who distinguish themselves in quality and output of work.

CANTEENS.

Many benefits are resulting, both to employers and workers, from the establishment of well-managed canteens. Among the former are improvement in the health and physical condition of the workers, diminished sickness, absence and broken time, less tendency to alcoholism, and increased efficiency and output; among the latter are the saving of time of the workmen, salutary though brief changes from the workshop, better midday ventilation, and, generally, greater contentment. The need for canteens arises especially in factories where, as so often happens at munition works, the workers cannot take their meals at home. In such circumstances the custom has been for the worker to bring his or her food, but this should be avoided, for, even when the factory supplies hot plates and warming cupboards, the choice of food is usually limited, and warmed up food is never so appetizing as freshly cooked food. Especially at night, when work is particularly exhausting, the food should be light and digestible, well cooked and attractive, for, lacking a full supply of nervous energy, the organs of digestion cannot deal with heavy, indigestible, and unappetizing meals. A canteen should have a well equipped kitchen and a dining-room, where cheap dinners of good quality can be obtained. Linked with the dining-room should be a club, providing rest, reading, and recreation rooms, gymnasium, baths, and if possible a roof garden, and rooms for educational classes and entertainments. Such a club should be part of the equipment of all modern factories and workshops. The service of meals in the dining-room should be quick. The worker buys a check, or a book of checks, and in the room finds a long serving counter at which he receives his chosen dish in return for a check. The meals are served hot and warm from hot plates beneath and behind the serving counters. The canteen should be open at all hours, and the hot meals served at times most convenient to the working arrangements of the factory. The management must be disinterested, and the workers should have a share in an advisory committee. In many factories it has been found that it actually paid to incur a loss on the meals served in the canteen, owing to the greater efficiency and health of the workers.

The canteen must be well ventilated and well lighted, and thoroughly aired between meals; it should be kept scrupulously clean, made to look as comfortable as possible, and the seats at the tables should have backs. The separate staff required for cooking, service and cleaning, in a canteen seating a thousand, is one head cook, and two under cooks, twenty assistant servers, four cashiers and ticket sellers, one storkeeper, and one assistant-store-keeper. At 150 canteens out of the 500 established, some 10,000 part-time voluntary workers have been employed; but this involves waste of energy, since it has been ascertained that fifty part-time voluntary workers are only equal to five regular paid assistants.

DIET.

An investigation into workers' food, made for the Committee by Professor Leonard Hill, has yielded some very interesting results. The loss of energy due to cooling of the surface of the body is greater than that due to mechanical work; an ordinary labourer may expend one-sixth of the amount of his total output as work and the remainder as body heat, whereas a sedentary worker may expend little energy as work, and almost all as body heat. As activity increases, the loss due to the latter cause grows out of proportion to the actual energy expended as work. Food should be taken regularly and not hurriedly, and the meals should be distributed evenly over the day. One of the earliest symptoms of fatigue due to overwork is digestive derangement; a tired man benefits by a brief rest before a meal. Professor Hill examined the diets popular with workers, male and female, young and old, estimated their content of protein, fat, carbohydrate, and tested them primarily by their yield in energy as expressed in calories. He examined the value of certain meals, taken at random as specimens of those served in canteens, students' clubs, and restaurants. The difference in price

is very striking. In a popular restaurant a meal of steak pudding, potatoes, and cabbage, and syrup pudding, yielding 1,344 calories, cost 1s. 5d. (79 calories for 1d.). In a factory canteen under amateur management a dinner of steak pudding, peas, and potatoes, jam roll, and rice pudding, cost 5d., and yielded 1,433 calories, or 288 calories for 1d. The cheap 5d. meal actually contained over 10 per cent. more protein than the meal that cost 1s. 5d., the same amount of fat, and rather more carbohydrate. The canteen dinners were generally good, yielding an energy value of about 1,000 calories, well distributed among the amounts of protein, fat, and carbohydrate. Inspection showed that meat, vegetables, and pudding were made of good materials and well cooked. The meals brought in by workers were found to vary a good deal more than the canteen meals. One man who brought rabbit and vegetables in a basin got only 683 calories; another man who brought sausage roll, bread-and-butter and ham, and cheese, got 1,448 calories; and a boy aged about 15 got 1,719 calories out of a dish of potatoes, tomatoes, and bacon, a jam puff, a cake, bread-and-butter and jam; but while this meal illustrates the effect of growth and work in producing appetite, the boy was probably over-eating if his other meals were on the same scale. The food of women workers was, on the whole, less satisfactory than that of men and boys, and the yield in calories was probably, in most cases, insufficient. A restaurant meal of roast mutton, potatoes, cabbage, and syrup roll yielded 687 calories, and cost 6d.; another in a teashop, consisting of a roll, butter, milk, sugar, stewed prunes, and syrup yielded 397 calories, and cost 7d. A meal brought from home yielded 590 calories, but another only 295. Whether deficiencies in the meal taken during the working period are made up by more liberal meals at home could not be ascertained, but, says Dr. Hill, "even if the home meals are more liberal, the distribution of the day's eating is on the wrong lines." He considers that in a long day's work there should be a good meal in the longest break if the efficiency of the worker is to be maintained for months and years. He accepts the estimate of numerous investigators that the energy required by a man engaged in fairly light munition work is about 3,500 calories of food as purchased; but where calculations are based, as in his report, on food as eaten, the minimum canteen diet should be taken to be about 3,000 calories, although for a man engaged in a sedentary occupation as little as 2,200 may suffice. An investigation was made of the diet supplied at a well-managed hostel, where each worker might eat as much as he or she desired. Four meals were supplied—breakfast, dinner, tea, and supper. Bacon or sausage, or both, were served at breakfast, either meat or fish at dinner, and either meat or ham, and cheese at supper. The calorie values varied between 3,847 and 3,913. This should satisfy the requirements of factory workers unless very heavy work is being done, and could be reduced somewhat if facilities for getting extra food were afforded to any one who wanted more. Five daily dietaries eaten by a well-paid worker, doing light work, yielded from 2,956 to 3,252 calories. In three of the five diets the largest number of calories was provided for midday dinner, the yield being 1,346, 1,102, and 1,003 respectively. In the two others the yield provided from breakfast was a little higher than that from dinner. In all diets the yield from supper was lower than that for dinner, and in all but two lower than that for breakfast.

(To be continued.)

WE learn from the *New York Medical Record* that Professor Savvin has recently published in the *Russkiy Trach* an analysis of the first 100,000 cases of wounds and disease admitted to the Moscow hospitals from October 3rd, 1914, to July 20th, 1915. The wounded numbered 68,321; the sick 31,571. It may be gathered that nearly 80 per cent. of the wounded were hit in the extremities, and it may be assumed from the experience in other fighting zones that a fair proportion of the injuries of the head and trunk were not severe; the conclusion seems warranted that the mortality among the wounded in the Moscow hospitals was not high. Of the 31,571 cases of disease 5,047 were infectious, typhoid fever heading the list with 1,701; there were 561 cases of dysentery, 68 of cholera, and 31 of typhus. In the majority of cases the patients were convalescent or in the post-infectious stage. Including bronchitis and tuberculosis there were nearly 5,000 cases of respiratory affections, and there were 586 cases of influenza.

SATURDAY, JULY 14TH, 1917.

THE EPIDEMIC OF POLIOMYELITIS IN NEW YORK, 1916.

THE rise and fall of epidemics has long been an attractive subject, and is especially interesting at the present time when the conditions created by the unparalleled war have led to extensive epidemics and to the appearance of diseases which, if not entirely new, had previously escaped recognition. Though unconnected with the war, the incidence of epidemic poliomyelitis is very definitely on the upgrade, and it is rather remarkable that in America, where the researches of Flexner and his colleagues at the Rockefeller Institute have so greatly advanced our knowledge, it is only within comparatively recent years that the disease has attracted much attention. Thus, in 1874, the disease was so rare that the leading consultants had seen very few examples. It is true that in 1907 New York was visited by a considerable epidemic, estimated by the investigating committee at 2,500 cases, with a mortality of 5 per cent., though positive information was obtained about 800 cases only. But otherwise, up to 1912, the deaths from this disease were so few in New York that they were not classified separately from "other diseases of the nervous system"; in the years 1912-15, and in 1916 up to June 1st, there were respectively 70, 54, 34, 13, and 6 deaths. Then a most extensive and virulent epidemic (June 1st to November 1st) of 8,928 cases with 2,407 deaths, or a mortality of 26.9 per cent., burst on Greater New York, a full account of which, based on the official reports of the Bureaux of the Department of Health, has just been issued.¹

This monograph is of value on account of the etiological investigations carried out during the epidemic, and especially for the full details of the vigorous campaign promptly organized against the disease; the discussion it contains would be of the greatest assistance to the sanitary authorities in the event of a similar disaster falling on other large cities. The recognition of the epidemic in June was at once followed by the institution of educational clinics for medical men, additional ambulances, medical personnel and hospital accommodation, inspections and house visiting, the circulation of leaflets, regulations, and bulletins, restrictions as to admission of children under 16 years of age to theatres, picture palaces, and meetings, and the control of children's playgrounds and travelling. Advisory and other committees were appointed and conferences held. The objects aimed at were "early diagnosis, prompt notification, hospitalization or equivalent home isolation, a well-informed public, and an alert medical profession." Isolation of the infected on the one hand, and of the healthy on the other, gave excellent results, and the period of quarantine for the former was raised from six to eight weeks. The case-rate per 1,000 of the population was 1.59, and, as judged

by the analysis of 1,325 fatal cases, 83 per cent. of the cases were under 5 years of age and 2.5 per cent. over 16 years of age; the mortality was higher among males and young children than among older children and adults. The day of the disease on which death occurred was noted in 1,848 cases, and showed that 1,510, or 81.7 per cent., died within the first week, 11.4 per cent. in the second week, and 3.2 per cent. in the third week.

The general belief that epidemic poliomyelitis has a greater incidence in rural than in urban communities was confirmed by the observations made in New York, which contains within its limits extreme examples of urban and rural conditions, the highest incidence in proportion to the population occurring in the least densely populated districts. From other etiological investigations it appears that dogs and cats were not affected by the disease and did not act as carriers of the infection; that food and drink, including milk, did not convey the disease; that there was no real relation between overcrowding and the spread of the disease; that the disease was communicated by personal contact, especially by slight and abortive cases, and that the incubation period is from three to ten days. An inquiry into the question of insect carriers by Professor C. T. Brues, covering twenty-seven pages, does not reach any positive conclusion. Repeated attempts to demonstrate the virus of poliomyelitis in the cerebro-spinal fluid of patients failed, and neither Flexner and Noguchi's globoid bodies nor Rosenow's streptococcus are accepted as the proved causal organism.

The diagnostic value of lumbar puncture and bedside examination of the cerebro-spinal fluid is insisted on; out of 1,500 cytological examinations of cerebro-spinal fluid, many taken on the second, third, or fourth day of the disease, there were 39 instances only in which the polymorphonuclears outnumbered the lymphocytes, thus controverting the view that in the early stage there is a predominance of polymorphonuclears. In rare instances red blood corpuscles were found evenly distributed throughout the cerebro-spinal fluid.

The following clinical classification is advised: (1) Non-paralytic or abortive, including the meningitic cases; (2) ataxic, very rare; (3) cortical, rare; (4) the ordinary spinal. The progressive cases, in which the arms are first affected and extension occurs to the legs and medulla, are regarded as instances of the condition commonly called Landry's paralysis, a rather novel view.

Lastly, from the full and interesting account of the treatment, the results of intrathecal injection of immune human serum from donors who had recovered from the disease may be quoted: out of 54 cases injected before the onset of paralysis, 44 recovered without paralysis; of the remaining 10 who manifested some paralysis, 5 recovered completely and 5 partially; out of 119 cases injected after the onset of paralysis, 8 recovered completely, 66 recovered partially, and 45, many of whom were in a desperate condition when injected, proved fatal. These figures are much larger than those (26) recently published by Amoss and Chesney,² who advocate both the intrathecal and intravenous injection of the serum. Clinically, the injection of serum is followed in the early preparalytic cases by intensification of the meningeal symptoms, while the cerebro-spinal fluid may become turbid and show a cell count of 10,000 per cubic centimetre, 95 per cent. being polymorphonuclears, although it is sterile.

ARMY MEDICAL ECONOMIES.

IN order to judge how far economies in medical personnel are still possible, a rough classification may be useful. According to their employment, medical men can be grouped into five categories, in each of which are to be found in varying numbers men of military age and men over military age. First, there are those exclusively serving the needs of the civilian population, and of them it scarcely need be said that most are working at full pressure, while not a few are continuously overworked. In the next group are those who combine with civilian practice part-time work of a military nature, such as the medical care of soldiers in voluntary aid and auxiliary hospitals, the examination of recruits, or service in Territorial general hospitals. Such part-time work enables many medical men who are well over military age to have the satisfaction of feeling that they are serving their country by assisting in the care of the wounded, or undertaking other duties which release younger men for active service. The increasing burden of safeguarding the health and relieving the sufferings of the civilian population rests on these two groups of practitioners, and from their ranks are recruited the medical men serving in whole-time military appointments, who, for convenience, may be divided into three groups.

It should perhaps be pointed out—if only in parenthesis—that a complete classification must take count of the naval medical service; but as this has remained since the war a fairly fixed quantity the considerable number of medical men employed therein may be set on one side. But in so doing it is only fair to remind critics of the Army Medical Service that the navy, although employing a large number of doctors, is practically immune from any question as to where or how it uses them.

Confining ourselves to the R.A.M.C. (Special Reserve, Territorial, and Temporary), there is first of all to be mentioned the group of officers who are doing a full day's work every day. It is common knowledge that there are in the corps a very large number of medical men who are fully occupied in posts for which they are well suited—clinical, administrative, or pathological, as the case may be. In a further group may be placed medical officers who, although occasionally hard pressed during rushes—which may be long or short, and may come often or seldom—are for the most part, week in, week out, working half time, or even less. Among these officers may be counted many of those employed in units on the lines of communication abroad, though we are aware that for some time past the medical work in some at least of the bases in France has tended to become heavier and more continuous. In this group also may fairly be placed the great body of battalion and battery medical officers serving with the armies in the field. Of their gallantry and devotion, and of the perils and hardships of their life at the front, we need only say here that these are never out of mind; our concern at the moment, however, is to indicate the groups into which medical officers fall in respect of professional employment.

Lastly, there are the medical officers in "whole-time" military service at home and abroad, for whom the military machine cannot, or does not, find anything like a full day's work; men who are condemned to long periods of inactivity whilst their services are badly needed in civilian practice. To the existence of this group is due most of the criticism which the Army Medical Department received from the medical profession and the public. We know from evidence

which cannot be gainsaid that there is such a group, but how large it is we do not profess to say. The military authorities justify its existence on military grounds. The exigencies of warfare, they say, demand a substantial reserve of medical officers ready for instant service at times and places which cannot be foretold. For these potential reinforcements, we are assured, employment cannot be guaranteed, and, if they were released for civilian work during the time of waiting, they would not be at hand at the moment when the army needed them. This, we believe, is a fair statement of the official view. The question at the present time is how far it can be maintained in face of the increasing urgency of the civilian situation.

Of the five groups enumerated above the first three scarcely call for discussion, for the members of each are, *ex hypothesi*, fully and usefully employed. It is only with regard to the fourth and fifth groups that there is room for disagreement or conflict of evidence. So much do these two groups shade off into each other that some critics would run both together, on the ground that it is idle to discriminate between degrees of incomplete employment. This may be logically sound, but for practical purposes at the present time the distinction can be usefully drawn. If economies in medical personnel are in any way to be brought about without detriment to the preservation of the health of the soldier, and his medical care when sick or wounded, efforts should first be directed towards reducing the numbers of the fifth group—that is to say, of medical officers "standing by" in idleness for long periods against emergencies which may arise, or holding appointments which manifestly never provide a full day's work.

It is easy to see that relative unemployment cannot altogether be avoided in time of war, and that a margin must always be allowed between ordinary and extraordinary demands. Hence we do not, for example, question the need for maintaining the full complement of regimental medical officers at the front, in spite of the fact that for considerable stretches of time the daily professional work of the battalion medical officer can often be got through in an hour or two. So, too, with the field ambulances at the front: their medical officers are periodically underworked, but equally they are subject to periods of overwork, while they serve at all times as reservoirs for filling gaps among the regimental medical officers. Suggestions have been made that considerable economies might be effected in respect of the field ambulances and of the medical officers of batteries by organization based on the corps instead of the division. With this purely military question we are not in a position to deal.

In the case of oversea base hospitals, which in their turn feed the medical units of the field armies with reinforcements, some surplus in officer personnel is clearly needed. But to secure due economy the amount of margin in this case should correspond not to any academic formula, but to the probable demands of the immediate military situation. Things may have changed already, but in the past there have been instances of overstocking at base hospitals and in medical units mobilized in advance of the needs of the moment. We trust that the somewhat disquieting statements which continue to reach us as to a superabundance of medical officers at certain centres abroad are based on inaccurate knowledge of all the circumstances; otherwise it is clear that economies are still needed in that direction. Further economies might also be effected among the medical officers of home units, either by a more general system

of part civilian and part military medical employment, or by grouping together larger bodies of soldiers for medical purposes, so that one fully employed medical officer might do the work of two or more who are now insufficiently occupied. We are well aware that there are administrative difficulties in the way of adopting these suggestions; these, however, should not prove insuperable if the co-operation which we have advocated can be brought about between the military and civilian medical authorities.

THE CENSUS OF 1911: DISTRIBUTION OF POPULATION.

I.

To many people the General Report on the Census of England and Wales in 1911¹ will seem belated. The crude figures of the enumeration have long been in use, while the age and sex distributions and occupational classifications have also been available for some time. The significance of the figures set out in the detailed tables can, however, only be grasped when the comparative method, which is of even more importance in statistics than in other branches of science, has been properly employed; it is the function of the General Report to institute such comparisons, and this duty has been most efficiently performed.

The first part is concerned with the rates of growth of different types of area. In rural districts the rate has increased from 2.9 to 10.2 per cent., while that in urban districts has declined from 15.2 to 11.1 per cent., as compared with the last intercensal period. Analysis suggests that this is due rather to residential and industrial developments—as strikingly illustrated in the growth of the outer suburbs of large cities—than to any change in agricultural conditions. At the same time it is noted that the proportion of the population engaged in agriculture in the rural districts of the seven counties which are most completely agricultural in character did in every case show an increase.

In the next section the sex and age constitution of the population is studied. The effect of the declining birth-rate has been temporarily advantageous in increasing the proportions living at the working ages. Thus, in consequence of the decline which began to be manifest in or about 1877, the 1901 curve showed a considerably greater proportion of persons in the age group 20–25 than did the previous census, but this advantage has now been lost, the proportion having become a trifle less than in 1881. Similarly, the first effect upon the next age group, 25–30 was to raise its proportion in 1891 and still more in 1901, but decline has now set in. It is remarked that “these fluctuations are not without importance in their bearing upon the probable future proportion in our population of workers at the most economically efficient ages, and especially upon the supply of recruits to the military services in future years.”

Six main types of localities have been recognized, namely: (1) Mostly ports and manufacturing towns; areas with an excess of both males and females during childhood and deficiency at nearly all adult ages. (2) Areas, chiefly mining districts, showing a similar distribution, save that the proportion of males remains above the average for the whole country to about age 45. (3) Industrial populations of a different kind showing an excess of males and females throughout the working period of life and deficiency in childhood and old age; the great textile towns fall

into this class. (4) A small group of suburban districts in and around London which show an excess in the first three quinquennia of life, succeeded by deficiencies during the fourth and fifth. Next follows a second period of excess at ages 25 to 45, and thereafter a deficiency. (5) In this group, comprising certain wealthy London districts and favourite seaside residential towns, the age distribution is most distinctive among females, their proportion being below the average during the first three quinquennia of life and above it afterwards. (6) The largest group, shows deficiency of young children and of young adults, a tendency to excess in later childhood, and great excess in old age of both males and females. Long-continued emigration and low rates of mortality would appear to be the determining factors in these areas, which include only four towns—Canterbury, Gloucester, Great Yarmouth, and Ipswich.

The section dealing with birthplace throws light upon the course not only of foreign immigration but also of internal migrations. The proportion of the native to the total population was greater than at any previous census—96.46 per cent., as compared with 96.13 per cent. in 1901, 96.14 per cent. in 1891, and 95.69 per cent. in 1881. Internal migrations are studied in various ways with the aid of shaded maps. The administrative counties with the highest proportions of native-born inhabitants are, as might have been anticipated, mainly agricultural, Cornwall, Cumberland, Lincolnshire, Norfolk and Suffolk being the highest, while the lowest places are occupied by mining and industrial districts or counties within the outer ring of great cities—Glamorganshire, Worcestershire, Warwickshire, Sussex, Surrey. The five metropolitan counties, Essex, Hertfordshire, Kent, Middlesex and Surrey, together with the county boroughs of West Ham and Croydon, contained upwards of a million natives of London. Of the four European countries sending the largest quota to this country—Russia, Germany, France, and Italy—Russia furnished the same proportion as in 1901, France rather more, Germany and Italy rather less than in that year.

The report contains statistics of infirmities and of languages spoken in Wales and Monmouthshire. The latter topic is not of medical interest and the former cannot, we think, be adequately studied by means of census returns. We concur with the view expressed in the report, that “while fully realizing the great importance of attempting to ascertain the numbers of persons afflicted with certain infirmities, we must submit that statistics of this nature obtained through a general population census are most unsatisfactory; first, on account of the difficulty of framing a suitable form of inquiry defining the degree of disability which it is desired to include in the tabulation, and, secondly, because the definition has to be applied by householders with no technical knowledge, who will interpret it in different ways, and many of whom have a natural reluctance to admit that they or their relatives suffer from any defect—at least to the degree referred to in the inquiry.”

We have, perhaps, said enough to make plain the great value of this report, but we hope to refer to some other subjects with which it deals in a later issue. The manner in which the national vital statistics of England and Wales are collected and analysed has always been able to stand comparison with those of any other country; it has been improved at each succeeding census, and that of 1911 worthily upholds a great tradition. Especial praise is due to the success achieved by Sir Bernard Mallet, Dr. Stevenson, and their staff under peculiarly trying conditions.

WAR BREAD.

IN last week's JOURNAL we printed a note on the report on "G. R." flour and war bread drawn up by Dr. J. Campbell for the Metropolitan Committee for War Savings. This indicated that the main reason for the variable taste and texture of war bread is the variability of composition of the regulation flour, and the difficulty in adapting methods of baking to the new conditions. At the invitation of the Food Controller a committee of the Royal Society is investigating the relation of war bread to the health of the community. At all times, but more particularly in hot weather, the making of bread by yeast fermentation has been attended by risks of souring, moulding, and the development of "rope," the causes of which are fairly well known. These risks are apparently increased at the present time owing to the changes in the material which has to be milled for use in bread-making. Thus both the miller and the baker have considerable difficulties to contend with in the production of palatable bread which will keep under present conditions. To the miller is set the problem of producing from maize and other cereals, with in many cases imperfect machinery, grades of flour which will blend satisfactorily with wheat and flour containing more of the outer part of the grain than formerly. To the baker is set the problem of baking bread from this composite flour, which differs in properties from that which he has been accustomed to handle. On the whole, both the miller and the baker have met these difficulties remarkably well, and there can be little doubt but that with further experience the troubles will be completely overcome. On July 9th a press conference took place at Grosvenor House, with Mr. Alan G. Anderson, vice-chairman of the Wheat Commission, Dr. A. W. J. MacFadden, chief inspector of foods to the Local Government Board, Mr. W. B. Hardy, secretary of the Royal Society, and Mr. Burton, chief of the bread section of the Ministry of Food. The main point insisted on by Mr. Anderson was that during the war, and perhaps for some time afterwards, the public must make up its mind to eating bread of a quality lower than in former days. The seriousness of the position with regard to the supply of breadstuffs cannot be over emphasized. The sheet-anchor of safety is the power of the Food Controller to compel the admixture of other cereals with the limited stocks of wheat now in sight. The suggestion that the mixture of flours should be standardized cannot unfortunately be adopted, since the wheats now being imported vary widely in milling quality, while the shortage of transport prevents a regular and uniform distribution of the grains used for admixture. Moreover, the principal supply obtainable from abroad, and near at hand, for the dilution of wheat is maize, for dealing with which few English flour mills were fitted with suitable machinery. By next year it is hoped that the difficulties in grinding maize for bread-making will have been overcome. There is no evidence that the energy value of war bread for the labourer is below that of pure wheaten bread. The change in bread known as "rope," of which there has been a good deal of complaint lately, is being investigated by the Scientific Committee. The micro-organism producing it (*Bacillus mesentericus*), is as common as dirt, and resists all practicable attempts at sterilization, since the spores survive five hours' boiling. It is not directly harmful to man and there is no foundation at all for the grotesque idea that "rope" is a disease of man. The development of "rope" is favoured, not by the added cereals, but by hot weather, by underbaking, and by the practice of covering the loaf with a damp cloth in order to maintain its weight. The gist of the matter is that with enough goodwill and trouble war bread can be made wholesome and palatable, and the public must be thankful that the position is no worse than it is. The complaints received very largely reflect the fact that this is the third year of an unprecedented war. The country is in a state of siege, and the supply of wheat is not enough to provide all the bread

needed. Admixture of other cereals less adapted than wheat to bread-making is an actual necessity of the country. These are the facts, and one of the most serious responsibilities of the medical profession is to assist the administration by showing that requests to the Ministry of Food for permission to use pure wheat flour cannot be acceded to, and that the refusal need not entail suffering. Up to the present the number of applications has not been large, but they may grow. The medical profession will render the country an undoubted service in co-operating with the Ministry of Food to prevent an abuse of the privilege. It may be pointed out that the applications come in much larger proportions from certain districts than from the country as a whole. Thus Hampshire, Yorkshire, Lancashire, Lincolnshire, and Cornwall furnish 64 per cent. of the number of applications from England—that is, nearly double as many as from the rest of the country.

THE MUSEUM OF THE ROYAL COLLEGE OF
SURGEONS OF ENGLAND.

THE annual report of the Conservator of the Museum of the Royal College of Surgeons of England contains, in addition to the information as to the war series described in the JOURNAL of June 30th and July 7th, a review of work of other kinds done in the museum. Professor Keith states that besides routine investigations carried on by the staff, Dr. Colin Mackenzie had not only continued his inquiries into the anatomy and physiology of Australian mammals, but acting also as a member of the honorary staff at the Military Orthopaedic Hospital, Shepherd's Bush, had found it advantageous to combine his work at the hospital with a research, bearing on his cases, in the workrooms of the College. The comparative anatomy of the muscles of the forearm appears to throw much light on their exact significance in man which may prove of value in surgery. The specimens of bone grafts which accompanied Major E. W. Hey Groves's Jacksonian Prize Essay are distinguished in the report as of particular merit. Many preparations of value have been added to the pathological, teratological, and particularly to the anthropological series; the latter include prehistoric human bones unearthed during trenching operations, not only in home drill but also at the front. The four complete skeletons of gorillas, each representing a different stage of growth, collected in the German Cameroons, and generously purchased and presented to the museum by Sir John Bland-Sutton, will provide an opportunity of illustrating various stages in the growth of that anthropoid which, in a structural sense, is man's nearest relation. Among drawings acquired by the museum is a sketch made for John Hunter representing a duck which had partially assumed the plumage of a drake, a subject in which he was greatly interested. Lastly, we may add that the executors of Dr. Robert Roxburgh have presented the original mechanical spray apparatus which Lord Lister employed in the Royal Infirmary, Edinburgh, and exhibited at the Plymouth meeting of the British Medical Association in 1871 during the course of his address in surgery. It had two nozzles attached to independent caoutchouc tubes, furnishing large clouds of spray, that could be directed, if necessary, to opposite sides of the part operated on. Dr. Roxburgh was Lister's last house-surgeon at the Royal Infirmary. Lister went to King's College, London, to fill the chair of clinical surgery in succession to Sir William Ferguson in 1877.

DIRTY MILK IN CLEAN DAIRIES.

RESEARCH institutes are busily engaged in the effort to attain to some satisfactory means of detecting the presence of the tubercle bacillus in the person and surroundings of the apparently healthy cow, and to devise schemes for minimizing the risks of contamination of milk. An interesting series of experiments by Dr. Stenhouse Williams, Mr. W. M. Scott, F.R.C.V.S., of Bridgwater, and

Dr. Roberts, M.O.H. Denbighshire, is recorded in a recent number of the *Veterinary News*. An attempt was made to prove the presence or absence of the tubercle bacillus in the faeces of cattle in dairy herds. While the microscope may show the presence of an acid-fast bacillus, indistinguishable from that of tubercle, the injection experiments, the various steps of which are described in details, do not seem to have given positive results except in a very small proportion of cases. Preparations made from the faeces of cows which had reacted to tuberculin failed to produce evidence of the disease in the guinea-pig. Incidentally, the report throws much light upon the common defects of farm accommodation for cattle. While dairies have been reformed, and often appear models of cleanliness, the cow-house and the cow herself are often as insanitary and as uncleanly as ever. Control by the tuberculin test is not carried to its practical conclusion, except by the largest herd-owners, and the advantages of maintaining a strictly non-tuberculous herd are only admitted in theory. The "purity" of milk is still judged by naked-eye standards only, and passage through a strainer is commonly regarded as sufficient proof. Although contamination by actual faecal or other coarse matter would seem to be of minor importance, the liability of milk to harbour all kinds of organisms in addition to the tubercle bacillus cannot be overlooked. A suggestion¹ for counteracting their influence by means of low temperatures has been put forward by Dr. Stenhouse-Williams and Miss E. C. V. Cornish, of the Dairy Research Institute, University College, Reading. The plan that they propose involves the provision of refrigerating plant at the railway collecting centre to which the contributing farms bring their milk, and refrigerator vans for its conveyance to the wholesale dealers in the large towns. By thus checking the activity of the microbes in the milk, it should reach the consumer in a fresher and more food-valuable condition than is the case under present methods. But such a reform in method must be expensive. The interests of the farmer, the contractor, and the dairyman will continue to prevail over those of the consumer, and nothing short of drastic legislation will suffice to bring about real reform, and so to save the health and lives of the thousands of infants who are being daily infected with tubercle throughout the country by the agency of dirty milk.

A STATE MEDICAL SERVICE.

An article advocating a State medical service was published in the *Westminster Gazette* of June 26th by "A Physician," who, having satisfied himself that we can never go back to the "haphazard go-as-you-please methods of pre-war days," that concerted action skilfully guided is essential against disease, and that a State medical service of doctors brings only a hazy conception before the public mind, boldly outlined his own particular scheme. The article was jauntily written, and far from accurate in many of its statements; no indication whatever was given as to how, with a "disciplined, organized, and well-led army of doctors," it could be arranged that "the same doctor would treat you as before." We doubt if the young physician's words produced any great effect on the public mind, but some answer seemed called for lest judgement should go by default. Accordingly, Dr. H. B. Brackenbury furnished a reply in the issue of the *Westminster Gazette* of July 9th, in which he dealt with some of the cruder and more objectionable conclusions in the previous article. He points out that it is not for selfish reasons that the medical profession is so nearly unanimous in its objection to a whole-time, salaried medical service. It is because they are convinced that medical practice reaches its best level when the family doctor relationship, as opposed to the State official relation-

ship, exists between practitioner and patient. Dealing with the alleged wish of some service doctors to escape the struggles of private practice, and their assumed willingness to become State officials, Dr. Brackenbury points out that against this must be set the vast numbers of men returning from the army who will insist on personal relationship with their own chosen doctor, and will not submit to the compulsory provision by public authorities of this or that practitioner. He says very truly that the medical profession in clinical practice is not attacking disease as an abstract entity, but is dealing with men, women, and children as human personalities. "Physician" seems to suffer from the antiquated form of muddle-headedness which confounds prevention with treatment. The present methods by which the State helps to look after the public health and to provide medical advice and treatment may be imperfect, confused, and wasteful; but the remedy lies not in a regimented State medical service, but in unification in central and local administration, together with expansion of the present scope of medical treatment. All this has been said before, but it has to be said again from time to time, because people will not sit down and think things out before they begin spilling ink.

THE RESEARCH DEFENCE SOCIETY.

THE Research Defence Society, owing to the continuance of the war, has again decided to postpone its annual general meeting. The committee's report of the work of the society during the past two years states that the inaction of the opponents of research had necessarily made the society less active. There had hardly been any controversy in the newspapers, and all through the country the great advances made in protective medicine due to research were being appreciated and better understood. The lectures given had been concerned more with the general influence of scientific medicine on the health and efficiency of the army than with experiments on animals. The Association for the Advancement of Medicine by Research decided last year in favour of amalgamation with the Research Defence Society, and the president and honorary treasurer of the association, Sir Thomas Barlow and Dr. Hale White, have joined the committee of the society. It is hoped that in the coming years there will hardly be any need for disputes with antivivisection societies, and that the society's best opportunities for usefulness will be found in wide, non-aggressive educational work.

EPHEMERAL LITERATURE OF THE WAR.

THE Report of the Library Syndicate of the University of Cambridge for the year 1916 makes a second appeal, the first having failed to meet with a satisfactory response, for the supply of the ephemeral literature of the war, which is so difficult to collect even now, and which it will be virtually impossible to obtain afterwards. Out of the list of thirty-seven magazines, some represented by sets, others by specimens only, there are three from hospital organizations—*The Craigleith Hospital Chronicle*, the *Gazette of the 3rd London General Hospital*, and *The Canadian Red Cross Special* (No. 7); and some speculation may attach as to the exact nature of *The Splint Record*. Among the attractive titles, *The Futile Fusilier*, *Spit and Polish*, *The Lead Swinger*, *The Dead Horse Corner Gazette*, may be mentioned. So far as medical publications are concerned an attempt is being made to form a complete collection in the library of the British Medical Association. It is interesting to note that the stream of German propaganda, which at the beginning of the war was directed to the Cambridge University library as though it were as an institution situated in Cambridge, Mass., has ceased to flow; but it had the effect of directing attention to this class of literature, of which, though a large quantity has been obtained from various sources, more would be welcomed.

¹ *The Milk Supply: A Suggestion*. By R. Stenhouse Williams, M.B., and Elfrida C. V. Cornish, M.Sc., Dairy Research Institute, University College, Reading. Pp. 10. Cambridge, 1917.

Medical Notes in Parliament.

Mesopotamia.

Court of Inquiry to be Appointed.

MR. BONAR LAW made a statement, on July 11th, as to the Government's intentions with regard to officers whose conduct has been impugned by the Mesopotamia Commission. That Commission was not a judicial body, its proceedings were not conducted under any recognized code, and the rules of evidence were not in all cases observed. There were two objections to procedure by court-martial: the one was that civilians could not be brought before it, while the Government felt that the conduct of civilians should be dealt with as well as that of military officers; the second was that every one of the witnesses who appeared before the Commission was indemnified, and therefore all the evidence would have to be taken afresh, which would mean a very long time. Moreover, action could not be taken on the evidence given before the Commission because the persons accused were not present all the time, and had no opportunity of calling witnesses for the defence. The Government had decided that a judicial court of inquiry into the conduct of all persons concerned was necessary in the interests of justice and of the individuals themselves, and would set up such a court under the Army Courts Inquiry Act, 1916. The Court of Inquiry would be composed of three officers and of two persons who hold judicial positions, one of whom would be the president. The case would be presented by the law officers of the Crown, or by counsel nominated by the Attorney-General. The proceedings would be open to the public except when the court otherwise decided, and all the parties interested would be entitled to be represented and to have their expenses defrayed out of public funds.

Medical Arrangements at Salonica.—In the House of Lords on July 10th, after a question by the Earl of Dunraven, the Earl of Granard said that he had returned from Salonica only a short time ago. At the back of that town there were hills where the climate was quite different from that in the Struma Valley, and six or seven camps had been established amply supplied with water. There was every reason to hope that the soldiers who had contracted malaria in the low-lying districts would benefit by a stay there. There was also every reason to hope that the condition of the sick and wounded at Salonica compared favourably with that obtaining in any other expeditionary force. He had visited every hospital in Salonica on many occasions, and every precaution had been taken. The Secretary of State for War said that, owing to the brutal policy of the Germans in sinking hospital ships, it had been necessary to change the whole hospital system, and, instead of sending the sick and wounded to Malta and Egypt and shipping as many as possible home, it had been considered advisable to shift the majority of the hospitals from Malta to Salonica. In addition seven general hospitals had been sent out from this country; there was also a convalescent camp at Corfu. He was assured by the medical officers that everything possible was being done for the sick and wounded at Salonica, and when the history of the campaign came to be written it would be found that the Medical Department of the War Office had done, or, at all events, had endeavoured to do, everything it could for the sick and wounded.

[The War Office issued a statement on July 11th to the effect that the health of the forces at Salonica this year compares very favourably with last. The fact is the more satisfactory as a large proportion of men now in the ranks suffered from malaria last year, whereas at the beginning of last summer the army was clear of the disease. The rates of sickness per 1,000 men during the four weeks ending June 23rd, 1916 and 1917, were as follows:

	1916.	1917.
Malaria and other fevers (primary cases) ...	7.79 ...	5.65
Dysentery and diarrhoea ...	20.55 ...	6.87
Enteric... ..	0.37 ...	0.02]

Manipulative Surgeons and Army Work.—Mr. Joynson-Hicks asked the Under Secretary of State for War whether he has yet obtained the promised opinion of the law officers as to the employment of manipulative surgeons and osteopaths; and, if so, what was such opinion.

Mr. Macpherson replied that the law officers found themselves generally in agreement with the opinion of Sir John Simon, Mr. Butcher, and Mr. Pollock, and were of opinion that, subject to conditions, the War Office might lawfully take certain action. They had advised, however, that the opinion of the General Medical Council should be taken before orders were given with a view to that action. Mr. Peto asked whether, if the vote for the Army Medical Service was put down for an early date, Mr. Macpherson would inform the House as to the final decision arrived at, and whether the Medical Council was going to place an embargo upon the employment of these manipulative surgeons for the relief of wounded soldiers. Mr. Macpherson replied that he would consider the question.

Retired Naval Surgeons in the Service.—Mr. Hohler asked whether the position of a naval surgeon, retiring before the war with a gratuity, was that the Admiralty had no further claim on his services, that, as a voluntary act on his part, he could place his name on an emergency list which, in case of his being called upon to serve, would entitle him to the rate of pay he was receiving when he retired, plus a bonus of 25 per cent., and that for this voluntary act he received no extra gratuity or reward of any kind; whether some ten or more naval surgeons who had retired before the war with a gratuity, and who had placed their names on the emergency list, had been called upon to serve, but were not receiving the pay promised, the Admiralty deducting from their pay a sum equal to the interest on their gratuity, and for a reference to any statute, regulation, or Order in Council made before the war that justified this; or, if not, for an undertaking that repayment of the sums illegally deducted, with interest at 5 per cent., would be directed to be made to these naval surgeons. Dr. Macnamara replied as follows: The position is as indicated in the first part of the question. On being called out he receives: (1) The rate of pay earned prior to withdrawal; (2) a bonus of 25 per cent. in lieu of any further retiring allowance. The gratuity paid on withdrawal is in effect a commuted allowance, and is comparable with the annual allowance paid to officers retiring under other conditions. The bonus is paid to both the emergency officer and the retired officer when re-employed, and as the latter has his retiring allowance suspended, it is consistent to deduct the annual value of the gratuity received by the former officer. The authorizing regulation is an Order in Council under which the Treasury has approved both the payment of the bonus and the deduction referred to. Any doubt as to the legality of the decision regarding the latter would, therefore, be equally applicable to the former. The annual value of the gratuity is calculated on the basis of the cost of an immediate life annuity at the date of withdrawal under the Post Office annuity table in force at the time. Mr. Hohler asked whether it was right to give a man a bonus, and subsequently charge interest on it when he rejoined on his own initiative. Dr. Macnamara said the heart of the matter is this: The gratuity is considered to be a commuted allowance. The officer retired on allowance, and re-employed got his allowance suspended. So it is deemed equitable to deduct the annual value of the gratuity from the officer retired on the same. Mr. Hohler then asked, has not the gratuity been used to get a practice, and Dr. Macnamara replied by inviting Mr. Hohler to argue that view before the Medical Director-General, the Accountant-General, and himself.

The Employment of Disabled Soldiers: Temporary Higher Pensions.—Colonel Sir Arthur Griffith-Boscawen stated, in reply to Mr. Byrne, that the great majority of disabled soldiers discharged found employment very readily, either directly or through local employment exchanges if they were capable of ordinary industrial work. If they required trade education, this was provided for them on application to local War Pensions Committee. If at the time of discharge the man's physical condition justified a higher award than that to which he was entitled under the terms of the warrant by reason of his permanent disablement, a temporary pension at such higher rate was allowed.

The Training of Discharged Deaf Soldiers.—In reply to Mr. Holmes, Sir A. Griffith-Boscawen, Secretary to the Pensions Department, said that the Statutory Committee had made thorough inquiries into the best methods of treating and training the deaf, and, with the assistance of the Board of Education in England and of the education officer in Scotland and Ireland, was arranging for the establishment of centres of instruction in lip reading. Very few deaf disabled men, however, had applied for instruction, or had accepted it when offered, and it was now proposed to establish a special aural board to get into touch with the men at the time of discharge or on renewal of pension, with a view of getting them to take the treatment or training most suitable for them.

Venerable Disease amongst Oversea Troops.—Asked by Mr. G. Greenwood whether the Home Office and the War Office had now come to an agreement as to administrative action to be taken to protect overseas troops from venerable disease, Mr. Bonar Law said the military and police authorities were already using such power as they possessed to deal with the evil; it appeared doubtful whether more could be done without legislation; but the matter was receiving constant consideration.

Nurses in Military Hospitals Abroad.—Replying to Colonel Yate, Mr. Macpherson said that the question of freeing nurses

in military hospitals abroad from non-nursing duties by the substitution of voluntary helpers for such unskilled work as nurses had to do, had been referred to the authorities in France. The only nurses not employed on strictly nursing duties were the home sisters, and they frequently had to nurse sick sisters.

Sanatorium Benefits in Ireland.—In reply to Mr. P. Meehan the Chief Secretary for Ireland said that the returns of expenditure made by county councils in connexion with tuberculosis schemes in Ireland indicate that there was a falling off in the estimated receipts from the Insurance Committees in respect of the treatment of insured and exempted patients in the current year as compared with last year. The consequent deficit would fall equally on the Exchequer maintenance grant and on the local rates. The question of grants for sanatorium benefit could only be dealt with by the Insurance Commission.

The Superannuation of Asylum Officers.—Mr. Brace informed Mr. Yeo that an order would be issued in due course, applying the provisions of the Asylum Officers' Superannuation Act to the officers of certified institutions, provided by local authorities under the Mental Deficiency Act. Some difficulties had, however, arisen which could only be removed by fresh legislation; in particular there was no power as the Acts stood at present to aggregate service in such institutions with service in asylums. The matter was not being lost sight of, but he was afraid it could not be taken up this session.

Army Medical Re-examination.

EVIDENCE BEFORE THE PARLIAMENTARY COMMITTEE.

The Select Committee of the House of Commons inquiring into the conduct of medical examinations under the Military Service Acts sat again on July 5th, Mr. E. Shortt, K.C., presiding.

Sir John Bland-Sutton.

Colonel Sir John Bland-Sutton, Senior Surgeon, Middlesex Hospital, gave evidence. He stated that last November, at the request of the War Office, he joined the Special Medical Board which dealt with cases in which a difference of opinion had arisen as to the fitness of recruits. Of this Appeal Board Colonel Lyndon-Bell was president, and at each meeting the president had the assistance of a physician and of a surgeon of long hospital standing. A meeting usually occupied two and a-half hours, during which eighteen or twenty men were examined thoroughly and carefully by a physician and a surgeon. The medical certificates and any papers which the men produced were laid before the Board. Each man was also examined by the president; the latter never pressed his opinion against that of the physician and the surgeon, but he was of great value to the Board in classifying recruits. The Board was a safeguard to the public in preventing invalids and unfit men from being passed into military service. At the same time it was very careful that unfair or unjust certificates should not be allowed to secure exemption from service for fit men. The Board was appointed in October, 1916, and down to July 4th had dealt with 3,449 cases. Of that number 289 had been raised in classification, 1,202 confirmed in classification, and 1,958 lowered. Of these 1,958 men 336 were rejected. This Special Medical Board had been duplicated in order to be able to cope with the work, and it sat twice daily.

The Chairman, recalling the remark of the witness as to certificates that were either "unfair or unjust," asked what proportion would he describe as hardly bona fide? Sir John replied, "About three per cent." The Chairman then referred to the number of cases—336—which (as already stated) the special board rejected, and inquired whether Sir John regarded that as showing a serious percentage of error on the part of local boards, and he said he did. Asked if he could form an opinion how that large percentage of error came about, Sir John said, "We think it is because these local boards have to examine a large body of men in a short space of time, whereas the men come to us with their certificates and the other facts available." The witness added that the principal condition which caused the special board to grant exemptions from service were epilepsy (48 cases), mental deficiency (29), tuberculosis (62), heart disease (97), and kidney disease (18). As to the raising of the classification, he said the recruits might have improved in the interval. He thought it advisable that the civilian element should predominate on boards. On the question of the relative value of certificates placed before the special board, the witness said that those of family doctors generally contained a dogmatic statement that a patient had some specific ailment and was unfit for military service, and the certificates given by specialists were, as a rule, all verbiage, and meant nothing, but the men paid double the ordinary fee for them. These generalizations by the witness, which were made humorously, brought laughter.

Mr. Pringle called the attention of Sir John to the statement made by Mr. Macpherson in the House of Commons,

that a man fit to do work in civil life was fit to do some work in the army. The witness replied that he could not accept that principle without qualification. A man with a weak heart might be a good stockbroker, and might make his fortune, but if he were put into the army he would drop down dead. Cases of that sort had occurred. There had been no striking increase in the percentage of rejections since the Committee was appointed. If the President of the Special Board found that a very glaring error had been committed by a local medical board, he wrote on the back of the paper relating to the case a note drawing attention to the fact. That had been done in a number of cases. In some instances the certificate was endorsed to the effect that the man should be employed at the work of his trade. The president had consulted the military authorities, and had satisfied himself that such recommendations were carried out as far as practicable.

Colonel J. T. Lewtas.

Colonel J. T. Lewtas (I.M.S.ret.), the President of No. 2 Travelling Medical Board, stated that between August, 1914, and April, 1916, he examined 7,500 recruits, acting alone; and since the latter date, as president of a board, he had examined about 35,000. He still saw each recruit after the man had been examined by each of the four members of his board. In the event of a difference of opinion arising the case was discussed, and, in the few cases in which the members failed to come to a unanimous decision, the opinion of the majority was accepted, or the recruit was sent for examination at a special hospital. That this practice appeared to have given satisfaction was shown by the letters written spontaneously by a number of recruits and by the acceptance of the decisions. Re-examinations were of value because in the early days of the war there were no medical boards, and the classification of recruits was made by one examiner, who was often inexperienced in that work, and because the condition of the men might have improved since they were first examined.

The sitting was adjourned until July 9th.

Surgeon-General Bedford.

At the sitting on July 9th the first witness was Surgeon-General W. G. Bedford, D.D.M.S. of the Northern Command. He said he had held the post for one year, and mentioned in the course of his evidence that in the twelve months ended June 30th thirty-three boards in the Northern Command had examined five hundred thousand recruits. A feature of their arrangements was the setting up of temporary boards, which visited munition works and other establishments. Local doctors, resident in the places visited, sometimes assisted. Speaking of the method of examination by the boards generally, the witness said a recruit had to run the gauntlet of a board, all the members examining for different kinds of disability; they expressed their opinion as to category and then the president decided what the category should be. The witness produced an Army Instruction that the president himself should classify all recruits. This was dated February 23rd last. The special medical board at Leeds was chosen by the War Office in London.

As to the constitution of the local medical boards, the witness, in reply to the Chairman, said that he endeavoured to get doctors who had been in the regular service to be presidents; they had had much wider experience of the conditions of military service and what was called for from the soldier. Temporary officers who had been in the army three years and had gained considerable knowledge of the army could now be obtained. The civilian doctor had been trained all his life not to look beyond the individual and had not raised his eyes to the horizon of his country's needs.

The witness disagreed with the opinion of Sir John Bland-Sutton that a stockbroker with a weak heart, though he could go on with his own business, would, if put into the army, drop down dead. If he was put into C 3 he would be as safe as a church. That was exactly the sort of man the army wanted to get—men of good education were most valuable. The witness, in reply to another question, said that he had been in the Regulars thirty-six years—all his time.

The attention of the witness having been called to a statement by Sir Alfred Keogh that it was difficult to get boards to understand that any one who could do anything in civil life could do that thing in the army, General Bedford said there was considerable difficulty. In this connexion he handed on to the Chairman a copy of a memorandum he sent last September to the presidents of the boards in the Northern Command. In this document he said: "I wish to call your attention to the very large

proportion of men found permanently unfit by some of the boards. The point I wish to emphasize is that every man found permanently unfit by a board is lost to military service, and cannot be called up for military examination for service of any kind." The document went on to say that every man who was of any potential use whatever for the army must be placed in one category or another. Some boards, it said, were allowing an enormous number of men to slip through their hands and be lost to the service. "This must now cease, and all boards must approximate their percentage to the lowest figures of the category appearing in the returns under review." The letter concluded: "This matter is one of cardinal national importance, and I appeal to the patriotism of all medical boards in this command to see that immediate effect is given to the spirit of this memorandum."

The witness was questioned at some length as to the reason for this instruction being issued. He put it that the local boards had not realized that there were so many trades in the army. The idea, he thought, was that because a man was in khaki he was going to fight. The Chairman said the witness could hardly suggest that boards did not know that all men in the army did not fight. He put it to the witness that the difficulty was that boards did not agree that men were fit to go.

On further questions, the witness said the memorandum was not issued on a War Office order, but it was issued after a meeting at the War Office, which was called because it was felt that through permanent rejections there was a preventable leakage of men who might be of use for the army.

The Chairman: Did General Keogh know you were going to send this out?—He must have known that we should do something to interpret the policy of the War Office with regard to rejections.

The witness afterwards read a document which he issued to the boards on June 26th last saying that his memorandum of September 16th had been unjustifiably misconstrued by some boards. Men were being passed into the army of no potential use whatever. The document continued:

I have been inspecting certain labour battalions, and I am shocked to see the specimens of humanity which have been accepted as of potential value to the army—men almost totally blind, deformed, of the poorest physique, men of doubtful intellect, men almost unable to stand, cases of severe and marked rheumatism, cases of paresis which rendered locomotion almost grotesque, several cases of insanity which told their tale at a glance. This scandal must be stopped at once. I shall hold officers personally responsible for passing any recruit who is manifestly unfit for any useful work in the army, and whose presence in it is an encumbrance. Moreover, it must be borne in mind that recruits below categories B 1 and C 1 are liable, if under a certain age, to be posted to reserve battalions for physical training, squad drill, etc., and this must modify the interpretation of the standards laid down. This question, like so many others, must be governed by common sense, and unless it be considered that a recruit is of some potential value to the army, and capable of performing some useful work, he should be rejected.

The witness was asked whether the issue of that letter was the result of any speech in Parliament, and he replied in the negative. It followed upon an inspection of labour battalions made by the Commander-in-Chief and himself. He did not receive communications as to what happened in Parliament. All he received were instructions from the Army Council. The witness added that the men he had inspected, and to whom his remarks applied, were the dregs of the whole command. In proportion to the hundreds of thousands of men passed by the boards the percentage worked out at a very minute one. In answer to Mr. Caradoc Rees, the witness said he was unable to recall the number of men to whom he had referred as shocking him because of their unfitness. He thought there were ten or twelve men wanting in mental balance.

Surgeon-General Jenkins.

Surgeon-General Jenkins, D.D.M.S. Eastern Command, said that after the War Office meeting in September, to which reference had been made, he issued an instruction to local medical boards, pointing out that there were many duties in the army which involved no greater fatigue than fell to the same men in civil life. He hoped that if the local boards realized this there would be a considerable reduction in the proportion of rejected men. The witness was asked by the Chairman whether his attention had been called to any of the pledges or promises given by Ministers in Parliament. He said it had not. His duty was to carry out the instructions of the Army Council. He had nothing to do with the pledges of Ministers.

Mr. Pringle asked the witness whether he suggested that the average clerk who was in C 3 category was better attended to in the army than he was at home.—I should think very much better in most cases. Mr. Pringle: So you regard the army as a sanatorium for these men?—In many cases I do.

The witness was asked whether he had received complaints as to Mill Hill Board, and said he had. There had been a lot of correspondence. Inspectors were sent down. Mr. Pringle: Were the complaints justified?—Utterly unjustified. Mill Hill has always been one of my best boards. The witness added that changes in the personnel of the board had been made, but not on account of the complaints. He was asked by the Chairman to supply the correspondence on these complaints, and undertook to do so.

The sitting was adjourned.

Surgeon-General W. G. Birrell.

At the sitting on July 10th Surgeon-General W. G. Birrell, D.D.M.S. of the Southern Command, was called. Since October, 1915, his experience in this area was that the percentage of rejections of recruits as unfit for the army was higher in the towns than in the country districts. This he attributed to the better physique of men in the rural districts generally.

The Chairman drew attention to the instruction issued by the War Office on September 24th, 1915, saying that "all doubtful cases of fitness for any form of service should be referred to the president for decision," and to the instruction of February last that the president himself should classify recruits. The witness thought this second circular was issued to ensure that the presidents of medical boards should see all recruits, and be responsible for their classification or rejection. He did not think that the presidents overruled the opinions of members.

The Chairman afterwards read the following letter from Sir A. Keogh, which it was said had been sent to Deputy Directors of Medical Service. It was dated July, 1915, and was as follows:

I wish you to regard what I say as confidential. It is imperative for you to get as many men as possible not fit for war service put into category as fit for garrison service abroad. We have so many civilian medical men working with us that you will have to be very strong in your action as regards the acceptance of their opinion when they reject men as unfit for garrison service abroad. This is a time when only very severe disability—heart disease and so on—should be regarded as rendering men unfit. All those disabilities which in peace time we have been accustomed to consider should now go to the wall—varicose veins, hammer toes, and a hundred and one other things which do not incapacitate men for ordinary garrison work.

I would not write to you on this subject if the matter were not one of primary importance concerning which Lord Kitchener was very anxious. Take it upon yourself to overrule decisions which place men in categories as unfit for garrison service abroad for disabilities only which do not incapacitate very completely.

The witness replied he had never heard of that letter before.

The Chairman next read a letter written by Sir A. Keogh after the meeting at the War Office in September, 1916:

Please issue orders to medical boards in your command that they are not to totally reject any man who can perform any kind of work without danger to himself or to others. Sedentary work does not mean clerical work only, it means any class of work which a man can do not involving the class of duty appropriate for other categories. Every man who can earn a livelihood in civil life can do something in the army, and it is perfectly ridiculous the continuance of these enormous numbers of rejections in each command. Will you please stop it at once, and give very definite orders to your boards.

The witness said that on receipt of this communication he sent a telegram that no man must be totally rejected who was fit to perform work in the army. He said in it nothing about comparative capacity for work in the army and in civil life. Replying to Mr. Sutton, however, the witness agreed with the statement that if a man was able to earn a living in civil life he was able to do something for the army.

Mr. Pringle read an Army Instruction sent out in February, 1917, that men were to be placed in categories for which they would probably be fit after four months' training. Asked if he agreed with that view, the witness said he should put a man in the category for which he was fit at the time, and if he improved put him up. Asked if the standard of fitness had been lowered since October, 1915, the witness said, "Not the standard of fitness; but some. Disabilities which used to cause the rejection of men were not now a disqualification." Mr. Pringle drew

attention to an official letter of May 13th, advising presidents of boards to inquire into the medical history of all recruits, and that in a case in which a history of feeble-mindedness was established, the man should not be passed. Asked whether he had been notified that in his command lunatics as well as blind and lame had been called up, General Birrell replied in the affirmative. There was always a risk, in calling up enormous numbers of men, that some who were not fit would be passed. To another question he replied that he had received an instruction that recruits suffering from venereal disease should be classified for the units for which they would be fitted after treatment.

Surgeon-General Culling.

Surgeon-General J. C. Culling, D.D.M.S. of the Scottish Command, was asked about a memorandum sent out to medical boards in his command in November last. In it he had referred to a memorandum issued by the War Office to guide boards in examining recruits on the point as to the amount of importance to be attached to heart murmurs. He emphasized the application of the principles laid down by the Army Council, holding that too much importance was attached to heart murmurs. The chairman read the document, as follows:

It may safely be said that a large number of medical men, as soon as they hear a heart murmur at once suspend further consideration of the question of general service or active work of any kind in the army, a procedure which would not be adopted by any practitioner in civil life as regards civil occupations. The argument is put forward of the personal danger involved to men with heart murmurs. It should only require to be pointed out that a soldier physically fit in every respect is in greater danger of sudden death in the fighting line than a man with heart murmur is at any time. Most careful consideration is therefore to be given to the possibility of men with well-compensated though structurally defective hearts rendering good service in the fighting line, and to the large question whether the danger to life is one to be met only by the physically perfect.

The Chairman put it to witness that his argument was that because a man was to be shot down in the trenches it would not much matter if he fell down dead from heart disease.—The Witness: He would not fall down dead from heart murmur.

The sitting was adjourned.

Surgeon-General Hathaway.

On July 11th, when Mr. Mooney was in the chair, Surgeon-General H. G. Hathaway, lately D.D.M.S. of the Western Command, gave evidence. Going over much the same ground as that covered by the previous witnesses, he said that directly he received any complaints he had them investigated. In the first instance he inspected all the boards, and he afterwards made inspection according to requirements. Following upon the conference at the War Office in September, he issued a notice to the presidents of the boards in the command as to the number of rejections, and undertook to forward a copy to the chairman. Witness afterwards referred to a War Office Order issued near the end of June, and mentioned by various witnesses, under which any men whom the officer commanding found unfit for military service were to be examined with a view to their discharge. The witness spoke of this in allusion to the camp at Oswestry, where such men were gathered together for the purpose of examination and discharge. The Chairman of the Committee put it to General Hathaway that the category in which a man served in the army was not really settled by the medical boards, inasmuch as after a medical board had classified the category could be raised by a medical officer and a commanding officer acting together. The witness gave assent. The witness was afterwards asked a number of questions in regard to the medical boards in Manchester. He had previously stated that it was the general rule of medical boards to come to their decision on the opinions of the members collectively, the president announcing the classification. The Hulme Town Hall board was the only one in Manchester in which the classification was made by the president alone. This had been stopped. The witness referred to the case of one board in Manchester where the president had been changed. He was a man exceptionally able and very highly qualified, but the fact that so many men were being passed into Class A attracted criticism. The witness was understood to say that in referring to the change of president he was not speaking of the Hulme board. He spoke in terms of satisfaction of the working of the Manchester boards generally. Mr. Pringle read a letter from a Liverpool doctor who said he was a member of one of the medical boards of that city.

We four civilian doctors examine the men, and then they pass into the president's room, where he sat alone. He accepts

or classifies them, and not one of us had the slightest idea what had happened to them, with the only exception of those two cripples who were absolutely rejected, and some dozen doubtful cases of phthisis. We examined in all just over 750 cases, and the other three doctors did not get to know the result of any case. I made it my business to find out by asking certain men to show their cards before they left the premises.

I collected 100 results, and analysed them. One man who served in the Boer war, and since had suffered delusions and depression, and has been twice in an asylum, was, after bringing a certificate from the asylum, put into class B 1.

Witness: That would be a case in which I should make a thorough investigation. I suggest that it should be sent to the general officer commanding.

Mr. Pringle said that the writer of the letter would be asked to give evidence before the Committee. The letter continued:

Two cases of epilepsy, in one of which I insisted on the production of the history sheet showing he had been previously rejected for epilepsy, were both accepted.

The witness said it was very difficult to give an answer as to these cases without local references.

Mr. Pringle referred to another case which, he said, was verified by an alderman at Colwyn Bay. Two civilian doctors put a man into Class C, and then a military doctor put him into Class A. His heart was so weak that after the smallest exercise he was of no use. Another case which Mr. Pringle mentioned was that of a man in Oswestry camp who had double rupture, and died within three weeks of being recruited. The witness said all these cases required thorough investigation.

The witness accepted the principle that a man who could earn his living in civil life could do some work in the army. He did not make a qualification. If special attention was required to dieting that could take place in the army. Mr. Pringle: Do you seriously suggest that the army allows these conditions for any man? Witness: That, of course, would have to be considered.

Mr. Sutton, referring to the case of a man rejected in September and since passed in Class A, asked the witness whether the standard had been lowered. Witness: The standard for eyesight has been slightly lowered, but otherwise I think it is rather higher than it was. Mr. Sutton then mentioned the case of a shoemaker who, previously rejected, was passed C 3. A few days later he was ordered into khaki. He could not put his putties on as the army could not find him any boots on account of his having to wear irons on his legs, and the result was that he was told to put on his civilian clothes again and that he could follow his own trade in the army. The witness said he had never heard of the case.

The witness stated that he took up his office as D.D.M.S. of the Western Command on July 6th, 1916, and ceased to hold the position in the last week in June, Surgeon-General Julian being then appointed.

Colonel Tyrrell, A.D.M.S., London.

Colonel C. R. Tyrrell, Assistant Director of Medical Service, London, gave particulars of the working of the medical boards in London, mentioning that where there was uncertainty as to the existence of diseases such as tuberculosis use was made of the hospitals for examination. The witness went on to refer to the allegations made against medical boards, remarking that the members were abused, and there was no one to say a good word for them. The military doctors could not write to the papers to correct what was said at the tribunals. Civilian doctors could, but at his request they refrained from doing so. In many cases it was only by talking it over with members of these boards that he had persuaded them to keep at their work. They kept on by reason of their patriotism and good feeling. If they refused *en masse*, as they would be justified in doing, recruiting in London would be stopped. In reply to the Chairman, the witness said his last observation referred to the civilian doctors. He and others in the army did not care.

Mr. Sutton during Colonel Tyrrell's protest said that the doctors on the boards disgusted members of their own profession; but later, in modification of the remark, he said his reference was not to the London district, with which, in fact, he was unacquainted. Colonel Tyrrell read a letter which was sent to the medical boards to the effect that the number of rejections for epilepsy was larger than was considered necessary.

"Certificates of civilian doctors," it added, "should not be accepted without the president of the board seeing the record. They should not be rejected unless the presence of scarred or bitten tongues and their general appearance lead the board to think that they are confirmed epileptics. A man who has an occasional fit and is capable of earning his living is also fit for work in the army, and should be classified C 3, if not considered suitable for higher categories."

THE WAR.

MESOPOTAMIA DISPATCH.

A DISPATCH from Lieutenant-General Sir Stanley Maude, K.C.B., Commander-in-Chief, Mesopotamia Expeditionary Force, dated April 10th, 1917, and dealing with the operations from August 28th, 1916, to March 31st, 1917, three weeks after the fall of Baghdad, was published in a special supplement to the *London Gazette* of July 10th. The first three and a half months was a period of preparation, the last three and a half one of action. During the first period the health and training of the troops, who had suffered severely from the intense heat during the summer months, was improved and supplies amassed. By the end of November the troops had shaken off the ill effects of the hot weather. During the second period the fighting was strenuous and continuous, and the strain imposed upon all ranks, both at the front and on the lines of communication, severe. They responded whole-heartedly to every call made upon them, and their reward has been the measure of their success.

THE MEDICAL ARRANGEMENTS AND HEALTH OF TROOPS.

General Maude observes that one of the features peculiar to this campaign is the length of the lines of communication putting exceptional difficulties in the way of the administrative service and departments. With regard to the health of the troops and the medical arrangements, he makes the following observations:

Since the termination of the hot weather the health of the troops has been uniformly good, and our well-equipped hospitals have been more than adequate to meet the calls made upon them by sick patients. Throughout the operations the evacuation of the wounded was carried out on model lines, and the arrangements made for the comfort and rapid transfer of patients from the field units to the hospitals on the lines of communication reflect much credit on those concerned. Whilst those on the lines of communication have done their share efficiently, the work of the medical services at the front has maintained its high reputation. During the operations the strain thrown upon all has been heavy, and the courage and devotion to duty displayed by the personnel on the battlefield has only been equalled by the zeal and energy of those in the field units. In this connexion the valuable services rendered by the consulting surgeons and physicians demand special mention, whilst the thanks of the army are due to the nursing sisters for their indefatigable services in tending the sick and wounded. These ladies have by their devoted work under difficult conditions of climate and surroundings set an example of which they may well be proud.

General Maude expresses his thanks to the individuals and organizations which, though not strictly military, have rendered valuable services to the army, placing foremost amongst them the British Red Cross Society, which worthily maintained its splendid record.

The sterling work performed by its personnel, and its bountiful provision of motor launches, motor ambulances and gifts, have been the means of alleviating much suffering.

The dispatch concludes with a statement that a list containing the names of officers, warrant officers, and non-commissioned officers and men whose services are deemed worthy of special mention will follow.

GLUE FOR APPLYING EXTENSION IN FRACTURES.

LAST August we published a note on a method of fixing extension to fractured limbs by the use of a glue adhesive, introduced by Major M. Sinclair, R.A.M.C., for use especially in the application of the extension to compound fractures of the lower limb. As we have received inquiries with regard to this, we have obtained information as to the formula at present used and the method of application. The formula in general use is as follows:

Ordinary glue	50 parts
Water	50 "
Glycerin	2 "
Calcium chloride	2 "
Thymol	1 part

The glycerin and calcium chloride are both deliquescent and take up the perspiration, which keeps the glue from getting brittle, and, more important still, allows perspira-

tion to take place. This prevents the skin from getting sodden, in which condition bacteria may flourish and give rise to skin troubles. The thymol is added to prevent putrefaction and diminish smell. Every time the adhesive is heated the odour gets less and less. Experiments have proved that bacteria do not grow on this preparation. Air-tight tins which hold about a pound are filled and sterilized at 100° and placed in store. When required the contents are melted in a water-bath, and set aside a few minutes to cool.

The adhesive is applied with the palm of the hand or a brush. The skin is washed with soap and sodium carbonate solution (four drachms to the pint) in order to remove fat, and when dry the adhesive is applied *without* shaving the part. The area is covered evenly, and the ordinary four-ply gauze as it comes out of the packet applied, having roughly measured the requirements and gathered it in at the level of the wrist or ankle. An alternative method is to put on a length of "Elastic cotton net bandage" (S. Maw) from knee to ankle, to glue it on the *outside*, and then to apply the gauze as above and bandage carefully with a thin bandage.

The gauze, being spread out fan-shaped, adapts itself to the conformity of the limb, and is kept in apposition with the skin by a loose woven bandage. The extension can be made almost immediately.

The above method of extension is a very great saving of time, and, when compared with the cost of good strapping, is as sixpence to three shillings a limb. The following slight modification in the formula gives an excellent adhesive which is a little more elastic:

Isinglass	50 parts
Glue	50 "
Water	50 "
Calcium chloride	2 "
Tannic acid	12 "
Thymol	1 part
Glycerin	2 parts

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Accidentally Drowned.

LIEUTENANT F. WHINCUP, R.A.M.C.

Lieutenant Frank Whincup, R.A.M.C., was accidentally drowned in France on July 2nd, aged 43. He was educated at St. Bartholomew's Hospital, and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1897, and that of F.R.C.S.Edin. in 1902. After filling the posts of assistant house-surgeon and house-physician of the South Devon and East Cornwall Hospital at Plymouth, of house-surgeon of Stroud Hospital, and of anaesthetist to the Shropshire and Mid-Wales Eye, Ear, and Throat Hospital at Shrewsbury, he went into practice in that town. He was physician to the Royal Salop Infirmary and medical officer to the Post Office and to the Board of Education. He had only recently taken a temporary commission in the R.A.M.C.

Wounded.

Major H. d'A. Blumberg, R.A.M.C. (T.F.).

Major L. W. Bond, Australian A.M.C.

Captain F. A. Hampton, R.A.M.C. (temporary).

Captain R. Johnson, R.A.M.C. (T.F.).

Captain R. L. Kenihan, Australian A.M.C.

Captain L. R. Meech, M.C., R.A.M.C. (temporary).

Captain E. A. Walker, R.A.M.C. (temporary).

Captain H. Young, R.A.M.C. (temporary).

Lieutenant J. Berry, New Zealand Medical Corps.

DEATHS AMONG SONS OF MEDICAL MEN.

Bowman, Leslie Spencer, Lieutenant King's Own Royal Lancaster Regiment and Royal Flying Corps, only son of Dr. Bowman, of Ulverston, killed June 25th, aged 20. He became lieutenant in September, 1916, and joined the R.F.C. the same month.

Crombie, James MacHattie, Second Lieutenant Royal West Kent Regiment, youngest son of Dr. Crombie, of Sidcup, Kent, died on July 2nd of wounds received on June 25th while wiring in front of the line, aged 20. He was educated at Epsom College, where he was for five years in the O.T.C., and was cadet officer and head prefect during his last year. In June, 1916, he gained a history exhibition at Christ Church College, Oxford. He went to the front last January, soon after getting his commission. His elder brother, Captain Ian Osborne Crombie, Middlesex Regiment, was killed on the Somme in July, 1916.

Lucas, Charles Leslie Clement, Second Lieutenant Northampton Regiment, youngest son of the late Mr. R. Clement Lucas, F.R.C.S., died of shell wounds on June 30th, aged 19. He was educated at Epsom College and at King's School, Rochester, and joined the army through Sandhurst.

Poole, Bernard Routh, Captain Canadian Army Veterinary Corps, whose death was reported in the BRITISH MEDICAL JOURNAL of June 2nd, was the youngest son of Surgeon-Major Poole, Bengal Medical Service (retired). He was born at Peshawar, educated at St. John's College School, Hurstpierpoint, emigrated to Canada in 1895, served for a while with the Canadian Dragoons, and had got an appointment in the Agricultural Department. When the war began he joined as a veterinary officer. He was killed by a shell while on duty with the Railway Corps.

Power, James Edward Clutterbuck, Second Lieutenant Royal Field Artillery, attached Royal Flying Corps, only son of the late Surgeon-Major E. R. Power, R.A.M.C., killed June 26th, aged 23.

Shears, Edward Hornby, Lieutenant Irish Guards, eldest son of Mr. Charles H. B. Shears, ophthalmic surgeon, of Liverpool, killed in action on July 4th, 1917, aged 26. He began his education at "The Leas," Hoylake, Cheshire, from whence he obtained a foundation scholarship at Bradford College, Berks. In 1909 he obtained an open exhibition at Trinity College, Oxford, and in July, 1913, gained a First Class in Greats (Litt. Hum.). In August of the same year he passed into the higher division of the Home Civil Service, and a year later became Principal Private Secretary to the then Postmaster-General. In May, 1915, he was allowed to join the army, and was given a temporary commission in the Queen's (Royal West Surrey) Regiment. In October, 1916, he transferred to the Irish Guards, going to the front in January of this year.

Young, Cyril R. M., Major Royal Garrison Artillery, son of Dr. Moffat Young, of West Hartlepool, died of wounds received on June 7th, aged 31. He was educated at Repton and at Loretto Schools, got a diploma at the Armstrong College, Newcastle-on-Tyne, and before the war was a consulting electrical engineer at Darlington. He joined the 3rd (West Hartlepool) Company of the Durham Unit of R.G.A. (T.F.) before the war, became lieutenant on February 12th, 1914, and had gradually risen to major during the war. He went to France with a siege battery, was sent home to train another, and returned to France last January.

MEDICAL STUDENT.

Hoey, Frederick Cyril, Second Lieutenant R.F.C., reported as accidentally killed on June 7th, was the son of Mr. Charles Hoey, of Shrewsbury Road, Dublin. Lieutenant Hoey was a second year medical student at the School of Physic, Trinity College.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

NOTES.

MENTIONED IN DISPATCHES.

A special supplement to the *London Gazette*, issued on July 6th, contains a dispatch from General Sir Archibald Murray, G.C.M.G., K.C.B., describing the operations of the Egyptian Expeditionary Force from October 1st, 1916, to February 28th last. Appended to the dispatch is a list of officers and others mentioned for gallant and distinguished conduct in the field and for other services. The following medical officers are included in the list:

Staff.

Colonel (temporary Surgeon-General) J. Maher, C.B., A.M.S. Colonels: C. J. MacDonald, M.D., A.M.S.; M. J. Sexton, C.B., M.D., A.M.S.

Lieut.-Colonel (temporary Colonel) O. L. Robinson, C.M.G., R.A.M.C.; Lieut.-Colonel E. J. R. Evatt, M.B., R.A.M.C. Majors: H. V. Bagshawe, D.S.O., R.A.M.C.; R. H. Bridges, R.A.M.C.; G. C. Taylor, M.D., R.A.M.C.

Captain (temporary Major) C. E. Hercus, N.Z.M.C. Captains: G. Dalziel, M.B., R.A.M.C. (S.R.); A. S. M. Macgregor, M.D., R.A.M.C. (T.F.).

Royal Army Medical Corps.

Lieut.-Colonels: A. Hosie, M.D. (ret.), G. Scott, M.B. (ret.), W. R. Matthews, M.B., H. W. Thomson, M.D.

Majors (temporary Lieut.-Colonels): M. Dunning, M.B., J. Evans, M.D., R. B. Hole, M.B., H. T. Samuel, G. A. Troup, M.D.

Major C. Kerr, M.B.; temporary Major A. R. Ferguson, M.D. Captains (temporary Majors): J. Aitken, M.B., O. C. P. Cooke, W. W. Greer, M.D., F.R.C.S.

Captains: J. A. H. Aitken, M.B., C. H. Allen, M.B., F.R.C.S., L. B. Baird, F. S. Bedale, M.B., M. Brennan, M.B., A. E. Bullock, M.B., J. Davidson, H. R. Dive, A. A. Gunn, M.B., W. T. Gardiner, M.B., F.R.C.S., J. Inglis, W. F. Mackenzie, M.B., A. A. McWhan, M.B., W. H. Milligan, A. F. B. Shaw, M.D., C. F. Searle, M.B., O. Teichmann, W. T. Torrance, W. D. Treves, M.B., F.R.C.S., P. S. Vickerman, M.B., R. G. Walker, M.B., A. P. Watson, M.B., F.R.C.S., T. Young, M.B.

Temporary Captains: P. H. Bahr, M.D., H. V. Leigh, M.B., R. B. F. McKail, M.B., F. J. McGlade, M.B., H. P. Sheppard, M.B., H. E. S. Stiven, M.D.

Temporary Lieutenants: F. J. H. Begg, M.B., F. W. Davidson, M.B., A. E. Harrison.

Quartermasters and honorary Lieutenants: R. S. Mason, H. W. Rose.

Temporary Quartermaster and honorary Lieutenant W. Deans.

Indian Medical Service.

Lieut.-Colonel A. J. Willcocks, M.D. (ret.).

Majors: R. W. Knox, D.S.O., M.B., T. C. Rutherford.

Captain R. B. S. Sewell.

Australian Army Medical Corps.

Lieut.-Colonels W. A. Fraser, R. Macdonald.

Captain W. Evans.

New Zealand Medical Corps.

Lieut.-Colonel C. T. H. Newton, M.D., F.R.C.S.

Captain R. L. Withers.

The list also includes the names of 51 non-commissioned officers and men of the R.A.M.C., 13 non-commissioned officers and men of the A.A.M.C., 1 temporary sergeant of the N.Z.M.C., 4 members of the Indian Subordinate Medical Department, 13 of the Queen Alexandra's Imperial Military Nursing Service Reserve, 3 of the Territorial Force Nursing Service, 4 of the New Zealand Nursing Service, and 29 of the Order of St. John and British Red Cross Societies.

England and Wales.

NOTIFICATION OF TUBERCULOSIS AND ITS RESULTS.

In many previous annotations dealing with the incidence and death-rate of tuberculosis we have called attention to the frequent failure to notify advanced disease until the actual end is approaching. This may be traced through numberless reports by medical officers of health in large and small communities, many of them proving that tuberculosis may remain unrecognized until the very last. In an interesting report for the year 1916 the tuberculosis officer for the borough of Middlesbrough is able to show a very marked improvement in this respect in his own district, and the figures that he presents are worthy of careful consideration. By the aid of the loyal co-operation of the panel doctors the notification of early cases has been very greatly increased and the number of those reported for the first time in their later stages has been proportionately diminished. There are still many such cases of concealed disease in which notification has been avoided, but, for the most part, early recognition has led to satisfactory treatment and, incidentally, to considerable financial saving. The tuberculosis authorities at Middlesbrough, having wisely decided to employ the limited funds at their disposal for the treatment of remediable cases only, have not relied entirely upon residential sanatorium methods, but have made use of home visitation and supervision to a considerable extent, and with very satisfactory results. The saving thereby effected has been notable, and at the same time the patients have been able to follow their regular employment without the interruption that residence in a sanatorium must entail. Incidentally, it is said to be inadvisable to transfer patients from indoor to outdoor occupations to which they have not been accustomed. The tendency to relapse would seem to be much greater in such cases than among those in which the normal occupation is resumed.

NATIONAL BABY WEEK IN BRIGHTON.

The national campaign against infant mortality was carried out with great vigour during baby week in Brighton and Hove. On Wednesday a baby show for the united boroughs was held at the Aquarium. The 700 infants present were divided into twenty-five classes, one for each month for girls and boys respectively and an extra one for twins; five prizes were given in each class. In addition awards were given to mothers for sewing, domestic work, etc. The average standard of the infants as regards cleanliness, nutrition, and clothing was excellent. After the judging, in which twenty-five doctors, assisted by nurses, took part, the prizes were presented at the Pavilion Military Hospital by the Mayoresses of Brighton and Hove. The limless patients much enjoyed the visit of the large concourse of infants. A visit was paid by the Mayor of Hove to the Hove Infant Welfare Centre, recently opened, when the Medical Officer of Health, Dr. Rawdon Wood, was able to show a most successful record of his few months' work, the attendances at the clinic reaching seventy in one afternoon. The Hove Crèche was also visited. It is hoped that the good work carried out here for so many years may be greatly extended as the result of forthcoming

legislation. Lectures on the importance of healthy babies to the State were delivered at all the schools, both elementary and private, in Hove by the teachers. Several thousand children entered for the twenty prizes offered by the Mayor of Hove for the best essays. Some of these were remarkable, showing a really intelligent grasp of the subject. In both towns exhibitions relating to child welfare were arranged.

MENTAL DEFECTIVES IN WORKHOUSES, ETC.

Regulations have recently been issued by the Local Government Board with reference to mental defectives received into Poor Law institutions under the provisions of Section 37 of the Mental Deficiency Act, 1913. The provisions of Articles 16 to 23 inclusive of the Order of 1913 with reference to the inmates of a sick ward, lunatic ward, or nursery are made applicable to the above cases, and the various notices of admission, discharge, death, escape, or recapture required by the Provisional Regulations under the Mental Deficiency Act, and copies of entries in the register of mechanical restraint are to be furnished to the Board of Control, together with periodical lists of all the defectives in the institution. It is the duty of the master to bring to the notice of the official visitors every defective who has since their last visit attained the age of 21 years, and leave of absence may only be granted to a defective by the guardians or the House Committee, except when the leave is for not more than forty-eight hours, which may be granted by the master with the concurrence of the medical officer. Owing to war exigencies preventing for the present the establishment of new Poor Law institutions for defectives, it seems unavoidable that vacant ward space in workhouses should be utilized for defectives, but it is to be hoped that this will be regarded merely as a temporary expedient and that special homes for this class may be provided as soon as circumstances permit.

MEDICAL INSPECTION OF SCHOOL CHILDREN IN LIVERPOOL.

The medical officer to the education authority, Dr. E. W. Hope, has published the report of the medical inspection of school children for 1916. The examination was confined to entrants and leavers; owing to the war the examination of the intermediate group at the age of 8 had to be relinquished. The number of children attending school in 1916 was 136,575; the average attendance was 118,788. The ratio was in 1916, 87.0 per cent., as compared with 87.4 per cent. in 1915. The total number of children inspected was 32,372, and, in addition, 9,762 special cases presenting defects were medically examined at the request of head teachers. School nurses are employed to attend at the clinics, and to visit certain of the schools with the object of promoting cleanliness and tidiness, and women sanitary inspectors visit the homes of neglected children, and of children suffering from medical defects that are being treated at home.

The figures as to cleanliness of head and body show continuous improvement as compared with previous years, but constant supervision is necessary in maintaining this desirable condition. Defective vision was present in 5.8 per cent. of the boys and 8.5 per cent. of the girls. Special defective vision classes have been instituted for the more serious cases, of which about two-thirds are due to myopia. A marked diminution in all forms of tuberculosis was noted at the routine examinations; only seven definite and eight doubtful cases of pulmonary tuberculosis were detected among 32,000 children, after careful examination by the school medical officers as well as by the tuberculosis officers. Of skin diseases, ringworm of the scalp was found in 426 children and ringworm of the body in 703 children. These figures show a decrease on the numbers recorded in previous years. At the end of 1916 the number of children away from school was 294, compared with 327 at the end of 1915. The number of cases treated by x rays was 129, including 17 carried over from the year 1915. There were a large number of cases of scabies—namely, 667 in 1916, as compared with 339, 512, and 555 in the three preceding years. Measles accounted for 7,686 cases, whooping-cough 1,524, and scarlet fever 1,195. The cases of whooping-cough and scarlet fever were fewer than in 1915, but the number of cases of measles was considerably more in 1916 than in 1915, owing to an outbreak in the spring and early summer of last year.

Fortunately the deaths from measles were below the average. During the past year the Education Committee at last grappled with the treatment of children suffering from enlarged tonsils and adenoid growths, and established a clinic with this object. It was opened in September, and twelve beds are provided to allow of children operated upon to stay the night. A charge is made to the parents, which is omitted in cases of penury; 224 cases were treated at the clinic during the four months since opening.

At the dental clinics 2,834 temporary teeth and 80 permanent teeth were extracted, and 562 temporary teeth and 113 permanent teeth were filled. Dr. Hope believes that during the summer, owing to the introduction of summer time, a number of school children suffered from insufficient sleep, especially in the poorer neighbourhoods where the children are not so well controlled. This may well be the case, as so many of the fathers are away on active service in the navy and army.

Ireland.

BABY WEEK CONFERENCE.

DURING the celebration of baby week in Dublin a conference was held in the Mansion House on July 4th, when Dr. E. Coey Bigger, Medical Commissioner, Local Government Board, gave an address on child welfare in Ireland. Arrangements in the past had been chiefly directed, he said, to the treatment of sickness by means of hospitals, the Medical Charities Act, the Poor Law, and National Insurance. In future the aim must be to place the public health system on a wider and wiser basis by directing energies to the prevention of sickness, not only by lessening infection but by increasing the natural resisting power of every child. At present infection spread from the slums where it was cultivated, and the abolition of slums would help to eradicate the diseases propagated there. One child out of every four born in Dublin died before the fifth birthday was reached; under proper conditions of sanitation, housing, careful supervision, together with sufficient and suitable food, the deaths should be reduced by 75 per cent., or, in other words, out of every four children who died three could be saved. When the deaths during the first year of life were analysed it was found that those in the families of the middle and upper classes were about one out of every forty to fifty children born, whereas in the families of the poor the deaths were about one out of every four children born, or, in other words, the deaths of the infants of the poor were about ten times as great as the infants of the upper classes. The children that went to make up this heavy death-rate would, if they lived, become in the ordinary course wage-earners, and consequently producers. This showed the extent to which industries suffered by this dreadful loss of what should be their greatest asset.

Dr. W. Maguire, Medical Commissioner, National Health Insurance, said that it was remarkable that in recent years, despite public recognition everywhere of the urgency of the subject, no legislation of importance affecting the health of the masses of the people had become law, with the single exception of the series of enactments known as the National Insurance Acts. How valuable was the weapon which the maternity benefit provisions of the Insurance Act placed in the hands of those interested in the welfare of motherhood was to be gathered from the fact that since January, 1913, when these benefits first became payable, a sum of at least £300,000 had been expended in Ireland on maternity benefit alone; while in addition it was estimated that a large sum had been expended in sickness benefit directly arising from the condition of pregnancy. The average number of insured women in Ireland was about 216,000. Of that number 35,000 were married, and 10,000 of them would have children—that was to say, about £15,000 was paid for maternity benefit. It therefore followed that £60,000 was paid in respect of the wives of married men to the number of 40,000; so that 50,000 women would benefit by the Act. Thus it would be seen that for the past four years an average sum of £75,000 per annum had been paid in maternity benefit to insured women and the wives of insured men.

Professor E. J. McWeeney, M.D., in discussing the

bacteriological control of milk, said that sanitarians were agreed that the high infant death-rate was due to the food of the child—the swarms of deleterious germs present in cow's milk, produced, conveyed, and stored under uncleanly conditions. He strongly advocated the compulsory chilling of milk down to 50° F. at the farm or cowshed, as at that temperature little multiplication of undesirable germs occurred. He supported municipal or charitable milk dépôts, and a bacteriological control of the milk supply. He held that the Public Health Department of a city like Dublin could not be considered up to date until it had established a special milk laboratory, worked by trained assistants, under the supervision of the city bacteriologist.

DUBLIN MATERNITY HOSPITALS.

The annual report of the Holles Street Maternity Hospital states that during the year 999 women were admitted to the wards, showing an increase of 75 as compared with the previous year; 645 women were admitted to the lying-in wards, the total number of births being 539; and 355 cases to the gynaecological department, where 246 operations were performed. In the extern maternity 928 patients were attended at their own homes, and the nurses paid over ten thousand visits to these women. At the out-patient department 2,500 cases were attended and treated. A special dispensary day is set apart for infants and expectant mothers, with the object of lessening the appalling infant mortality of the city.

The Coombe Hospital has received a donation of £25 from the Queen, who visited the hospital in 1911. The Board is making a very earnest appeal to the benevolent public to meet the pressing needs of the charity, which has a debt of over £6,000. The work of the hospital is carried on amongst the very poor, and through its instrumentality much suffering is relieved to women and infants in its wards and dispensary.

Scotland.

NATIONAL INSURANCE IN SCOTLAND.

At the annual meeting of the Scottish National Conference of Friendly Societies, held in Edinburgh, motions were adopted calling for the establishment of a separate department of the Ministry of Health in Scotland, and reformation in the administration of the problem of housing. Sir James Leishman, chairman of the Scottish National Commission, in the course of an address on insurance administration, said that many persons had joined, and there had been a large number of changes in occupation. Married women had re-entered insurance and retired men had taken up some kind of work. About half of the medical profession and 60 per cent. of chemists were doing war work, and 80 per cent. of the staff of the administration were on military service, as were also a large proportion of insurance members. The total amount of money collected from all sources was twelve and a half millions, and seven and a quarter millions had been expended in benefits or in administration; four and three-quarter millions had been invested. Complaints in connexion with the administration had been reduced by 40 per cent. He concluded by expressing the opinion that everyone should realize that a broad national policy should be adopted in the matter of insurance.

EPIDEMIC DIARRHOEA.

The Local Government Board for Scotland has issued a circular to local authorities and medical officers of health on the excessive mortality among children arising from epidemic diarrhoea during the summer and autumn months. The Board urges upon local authorities the great importance of taking all practicable measures for the prevention of this disease, and for the promotion of hygienic conditions in the feeding of infants. It attaches much importance to special visits paid to mothers by health visitors during the season in which epidemic diarrhoea is likely to prevail, especially in the homes in which there are hand-fed infants. It is urged that during the summer and autumn months temporary health visitors should be appointed to devote their whole time to the organized visitation of cases of epidemic diarrhoea, and to

the instruction of the mother or guardian in precautionary measures to prevent its spread. Half the salaries of health visitors appointed for this purpose would be repaid to the local authorities under an approved scheme.

Correspondence.

DR. ADAMI'S CROONIAN LECTURES.

SIR,—It would take an undue amount of your space and of my time were I to state fully the grounds which I have for regretting the tone and the matter of Dr. Adami's two Croonian lectures published by you in your issue of June 23rd. Nevertheless I ask your permission to lay them briefly before your readers. Those grounds may be classed as matters of taste and matters of fact. With regard to the first, Dr. Adami offends (a) by citing without my permission (and in a garbled form) a private communication made by me to him; (b) by professing that "the time is ripe" for him to instruct the biological world in elementary facts as to the experimental modification of the activities and forms of pathogenic bacteria which (as I had pointed out to him) are really familiar to biologists, and are not and never have been—as he persists in asserting, in spite of plain information to the contrary—treated with "superb indifference" and neglect in this country; (c) further, by comparing Professor Bateson, for the purpose of vulgar ridicule, with a bumble-bee in a greenhouse; and also (d) by making use of the unworthy method of *suggestio falsi* in recklessly stating that the evolution of a new property by direct acquirement is "contrary to the hypotheses and dogmas of Professor Bateson and Sir Ray Lankester." My objection to this is that Dr. Adami must know, if he knows anything about the matter, that Professor Bateson's views and mine on this subject have little in common. It is unfair to both of us to suggest that they are identical, whilst it is merely rhetorical abuse to speak of those views as "dogmas." Further, it is the fact that Dr. Adami was categorically informed by me eighteen months ago that the frequent evolution of a new property in a race of bacteria by "direct acquirement" was maintained by me forty years ago, and supported by facts published by me and at that time novel, concerning the peach-coloured bacterium (*B. rubescens* or *rosco persicinum*) and the frequent pleomorphism of the bacteria, and that I, in common with many other biologists—including my regretted friend, Elie Metchnikoff—have continued to hold and advocate that view in spite of the adhesion of "medical bacteriologists" to Koch's doctrine of the fixity of bacterial "species."

Dr. Adami now endeavours to give his Croonian lectures a flavour of novelty by claiming for some medical bacteriologists who have recently accepted the long-known views of myself, Warming, Zopf, and Metchnikoff, the merit of a new discovery. He actually, at this late hour of the controversy, sets out, whilst announcing himself as a "militant" reformer and missionary, to teach *us* what we have done our best to teach *him* from his student days onwards.

So much for matters of taste. Now as to some of the matters of fact misrepresented by Dr. Adami.

(a) Under the heading, "Nature of variation" (p. 838) Dr. Adami confuses the terms "variation" and "variability," and thereby renders all his argument "suspect." No one disputes (as Dr. Adami asserts that some do) that *variability* is a primary quality of living matter inherent and not acquired. On the other hand, no one denies that actual *variations* are brought about by the influence of forces acting from without upon this labile variable living matter.

(b) Further on (at the top of p. 840) Dr. Adami states that I deny that there can be external influences of such a nature that specific variation may be induced by them. I have never at any time denied, but on the contrary always maintained, the truth of this elementary proposition. Biologists do not require Dr. Adami to pose, as he says, "under the shade of Harvey," and to cite well-known facts in order to be persuaded of this. It is really unfortunate that Dr. Adami should pretend that these facts are unknown to those whom, with some cryptic implication, he terms "academic biologists."

(c) Moreover, Dr. Adami is hopelessly wrong in his use

of Herbert Spencer's term "direct adaptation." He says that the worker in pathogenic bacteriology is impressed with the fact that "direct adaptation" is one of the basal phenomena of living matter. This is the great discovery which he thinks it his duty to teach to academic biologists. He is singularly unfortunate, for he proceeds at once to show that he has never understood what Herbert Spencer meant by "direct adaptation." Dr. Adami says that direct adaptation is "specific modification in response to a specific alteration in environment." That is not so. As Mr. Herbert Spencer is at some pains to point out, a specific modification in response to a specific alteration in environment is not necessarily an "adaptation." It may in certain cases happen to be so, but on the other hand it may have no such quality. Such a modification may be destructive of the life of the organism, or it may be disadvantageous rather than adaptive, or it may be, so to speak, neutral and without significance. Such specific modifications in the case of the simplest living matter have, it seems probable, never been *directly* adaptive, but some of the many modifications so set up would, *under some of the many further changes of environment*, prove of value in the struggle for existence to the primitively simple living thing so modified, and would lead to its survival by natural selection. This is called by Mr. Herbert Spencer "adaptation by *indirect* equilibration" as contrasted with "adaptation by *direct* equilibration." I need not pursue the subject further. It is sufficiently clear that Dr. Adami is under the illusion that mere modification of an organism in response to change of environment is described by the term "direct adaptation," which it is not. Accordingly in this case also, as in regard to the words "variation" and "variability," he misunderstands what other people have said on the subject on which he lectures, and, in consequence, solemnly gives utterance to propositions which have no serious meaning.

(d) Dr. Adami proceeds to maintain that the retention of its changed character by a strain of experimentally modified bacteria multiplying by fission is an example of the "transmission" of an acquired character. He is probably aware that it is very widely admitted that no case of the transmission of what are called "acquired" characters from parent to offspring has been demonstrated in so far as those higher animals and plants which multiply by means of specialized egg cells and sperm cells are concerned. The well-known retention of induced change of character in very simple fissiparous organisms does not go far towards rendering it probable that transmission occurs in the case of elaborate multicellular organisms with specialized reproductive cells. Dr. Adami offers us a dissertation on the word "individuality," which is of no assistance in the matter, and later proceeds to state that Weismann "violently opposed" the doctrine of the transmission of acquired characters. This is a baseless charge. Weismann was a patient investigator, and anything but a "violent" controversialist. He came to the conclusion that not only had no case of such transmission on the part of higher organisms been demonstrated, but that the mode of development and structure of the reproductive cells was such as to make it improbable that such transmission could be brought about. Nevertheless, Weismann would have examined fairly and judiciously any attempted demonstration by a competent investigator of an instance of the transmission of such characters, and so at any time would "the academic biologists" of this country. Weismann would not have been interested in Dr. Adami's recent orations, since he was well acquainted with the life-history of both Protophyta and Protozoa.

It would not be right, since Dr. Adami has made a point of alluding to me, that I should leave his statements unnoticed, as I should have done had he not referred to me by name.—I am, etc.,

London, W., July 4th.

E. RAY LANKESTER.

SUGGESTIONS FOR A MINISTRY OF PUBLIC HEALTH.

SIR,—No excuse need be made in putting forward now a scheme for a Ministry of Public Health to form a basis for discussion, because such a scheme is both necessary and non-existent. After the war it will be clearly Medicine's duty to formulate proposals for such a co-ordination and carrying out of all medical services as shall not only maintain but promote the health of all classes in

all parts of the empire, both in peace and war. Such proposals will necessarily involve a Ministry of Public Health framed on sound lines. I submit the following:

The Minister—a medical man, because no other can safely state the needs of his ministry to the Cabinet, Parliament, or the public.

A Council of Thirty Members—12 medical, 18 lay—constructed thus:

Twelve Medical Members:

Director-General of Sanitary Service—this Service including "Public Health," "Tuberculosis," "School," and "Maternity and Child Welfare" Services.

Director-General of State Insurance Service, in which the Poor Law Service should be merged.

Director-General of R.N.M.S.

Director-General of R.A.M.C.

Director-General of I.M.S.

Director-General of Colonial M.S.

Director-General of Medical Education.

Two Representatives of Civil Hospital Service, one a physician, the other a surgeon.

Three Direct Representatives of the Medical Profession, one a man.

Eighteen Lay Members:

Two women.

Two civil hospital governors.

Two representatives of labour.

One representative each of the Board of Education, the State Insurance Board, the Admiralty, the War Office, the India Office, the Colonial Office, and the Treasury.

Five members appointed by the House of Commons.

By such a scheme, it seems to me, each department of service would be adequately represented, consistently with due compactness of the Council, the necessary dominance of the lay element would be ensured, and its composition closely fitted to the needs of the Ministry, checks would be provided against faddism, either lay or medical, and the needful connexion with other Government departments formed.

The "civil hospital service" would include the charge of asylums, dispensaries, and perhaps of the Home Civil Service Medical Service. Otherwise I think the list explains itself.

The scheme is, as I say, offered as a basis for discussion. We cannot begin too soon discussing such a Ministry.—I am, etc.,

Exeter, July 7th.

W. GORDON.

MEDICAL STUDENTS IN AND OUT OF THE RANKS.

SIR,—There must be many medical men in a similar position to me as regards their medical student sons now serving with the army abroad. Take my case as illustrative. A country doctor, with a family of sons, anxious to get one of them qualified, to help him when he gets past work, or to help the mother, or his younger brothers in case of need. The eldest, a student of medicine at 16½ years old, after one year at medicine was in khaki, and before 18 in the firing line in Flanders, and now when over 20 still there. A second son follows in his wake, and so on.

The other side of the picture is to be seen in some of the medical schools. Lads who became students after the war broke out, who are unfit for general service, are allowed to remain at their studies, and are now in their third year, perhaps have passed two professional examinations and may be qualified, and either officers in the R.A.M.C. or practitioners earning a good income, while my sons are still first-year men and still fighting.

These "unfit for general service students" will in most cases be quite fit to carry on a hard working practice in opposition to the lads who return—those that are left of them alive or not permanently crippled. I sometimes picture my own practice, which I have worked hard to develop and tried to keep in my family, one day in possession of one of these men, who have done nothing for their country, instead of in the hands of my own son. If this war goes on, all my sons will have to go in time, and it is a terrible sacrifice to contemplate with no compensating conditions. I am not grumbling, but I am wondering if this is all quite right. What is going to be done for these fighting medical students when they return to find their places taken by the kind of men I refer to? Many of these so-called "unfit" can work as vigorously at home and as long hours as most perfectly "fit" men can, and many of us would like to know what really is the matter with them

that they are "unfit." If they are "unfit" for any kind of army service, it seems safe to say they are also "unfit" for the strenuous work of a medical practice as I understand it.

We have paid fees for a medical education which may never be got, and it is terrible to think that these lads may return at perhaps 24 or more years of age to begin their first year to find their "unfit" competitors qualified and flourishing who began their studies after they began to fight for the country. I may be wrong, but it is not in accord with my sense of justice.—I am, etc.,

July 2nd.

"AUX ABSENTS LES OS."

THE CO-ORDINATION OF BRITISH MEDICAL POLICY.

SIR,—A number of letters have recently appeared in the JOURNAL on this subject, and to me the general tone of them is that the attendance upon the less well-to-do needs organizing to a further extent than has hitherto been done. With that view I fully agree, but I am prepared to advocate a much greater step than has been suggested in the last few weeks as an ultimate goal, not in one step.

We must as a profession remember that we are largely conservative in political matters; that we look at the question from within a more or less carefully guarded enclosure; that, after all, we are public servants in so far as we are responsible for the health of the nation, being looked to for advice both publicly and privately. That we respond to our obligations in the vast majority of occasions is a credit that I believe no one will dispute. But if we assume so much responsibility must we not also assume more, and consider whether it is not possible for the mass of the people to obtain still further benefits from us, irrespective of whether it is to our financial advantage or no? If it is allowed that the State should look after the education of the people, can anyone dispute that the health of the people is still more a matter for State regulation and control? If not, then there should be no interference with medical practice by the State, probably not even the question of registration. But if yes, then it must follow that the majority in the State must have the right to regulate medical matters as far as it seems to that majority that improvement is possible in the health of the people, even to the extent of providing it out of State funds, of nationalizing the hospitals, the education and examination of students, and anything else that may be needed.

But that is a long cry from our present condition, and could not be done all at once. I doubt whether any of those of us who advocate a national service expect to see it working in a fully developed form during our lives; we only hope to see it started.

The first step seems to me to be the establishment of the Ministry of Health that we are promised, so that there may be a central authority to control medical matters in their entirety. Any form of medical attendance under the Insurance Act could best be under it. Health officers, tuberculosis physicians, Poor Law medical officers, infant and school medical officers, and all the other specialized importances would be under the Ministry. Hospitals and sanatoriums could better be provided under it, and many more of them are needed, especially "cottage" hospitals, where cases could be admitted for rest, as apart from cases requiring skilled surgical or specialized medical treatment. Provision ought to be made for women and children to receive treatment from the public service; drugs should be provided at the public dispensary, and not bought from a chemist in the manner now done under the Insurance Act; it is too extravagant, as every one in an industrial practice knows.

There is one remark I should like to contradict in the past correspondence. It is said that the "fiasco" was due to men being bribed from their allegiance to the Association. No such thing. It was due to the Representative Meeting passing a resolution telling us to go and make terms with the clubs after the chief cry for months had been "no more clubs"; it disgusted us, and we had no desire to remain in an organization which could fool us in that manner; such was my own feeling, and others expressed the same. Our resignations were not accepted; mine was not, at any rate.—I am, etc.,

Mumbles, July 9th.

F. DE COVERLY VEALE.

QUO VADIS (VEL CUI BONO)?

SIR,—I agree with Dr. Fordyce's dictum that the disciplinary control of the entire body of registered medical men cannot be secured by any known means. For this reason I have retired from medical politics. As a "farewell" I must, however, nail to the counter Dr. Fordyce's statement that Mr. Lloyd George and his subordinates had ready, in the event of a strike by the profession on the introduction of the Insurance Act in 1912, a whole-time service scheme, and the necessary staff to work it. It was a bluff pure and simple—*pace* Dr. Fordyce. The proof is, that in the one tiny area which held out neither Mr. Lloyd George nor his subordinates could find the necessary staff to work even this minute section. The real truth was that the financial inducement finally offered was good and sufficient, and the terms on the whole honourable and satisfactory. The vast majority of panel practitioners to-day are of the same opinion still—again *pace* Dr. Fordyce and the whole body of *extra*-panel practitioners, whose opinion on panel matters is valueless.—I am, etc.,

Hove, July 8th.

RAWDON WOOD.

BENEDICT'S TEST FOR SUGAR IN THE URINE.

SIR,—I have lately received a number of complaints from medical men that they have been unable to obtain satisfactory results when testing urines for sugar with the Benedict solution supplied to them by local chemists. On inquiry I find that in every instance the solution had been prepared according to the directions given in a trade publication, and that this solution is that described by Benedict for *quantitative* work, although the fact is not stated. It may be helpful, therefore, if I point out that Benedict's *qualitative* solution, employed in testing for sugar, is prepared as follows:

With the aid of heat dissolve 173 grams of sodium (or potassium) citrate and 100 grams of anhydrous (or 200 grams of crystallized) sodium carbonate in about 700 c.cm. of distilled water. Dissolve 17.3 grams of pure crystallized copper sulphate in about 100 c.cm. of distilled water. Cool the solutions to the temperature of the room, pour the second into the first, slowly and with constant stirring, make up to 1,000 with distilled water.—*Glycosuria and Allied Conditions*, p. 33.

The difficulty of having two separate and distinct solutions for qualitative and quantitative work may be avoided by employing the modified Benedict solution and method of estimating sugar in the urine I recently described (*Lancet*, April 21st, 1917, p. 613).—I am, etc.,

London, W., July 3rd.

P. J. CAMMIDGE.

EARLY SPLINTING IN GUNSHOT WOUNDS OF THE MANDIBLE.

SIR,—In Mr. Colyer's note on the treatment of gunshot wounds of the mandible he places fixation of the parts last and says that "to adapt splints in a 'field of sepsis,' as is so often done, is to ignore the most elementary surgical teaching."

I yield to none in my admiration of Mr. Colyer's crusade against sepsis in the treatment of these injuries, but I cannot think that he means that no fixation of any kind should be attempted until sepsis has been controlled. The constant movement of the fragments which in many cases accompanies every attempt at speech and deglutition is a potent factor in keeping up sepsis, to say nothing of the misery it entails on the patient.

The device used to keep the fragments still may, and by reason of the illness of the patient often must be, of the simplest, sometimes no more than a ligature of wire or silk; and it goes without saying that, whatever it may be, it should allow of free cleansing and in no way impede the irrigation of the parts.

If these points be borne in mind, early fixation, regardless of the presence of sepsis, is at once followed by diminution of discharge and increased comfort of the patient, as no one who has tried it can doubt for one moment.—I am, etc.,

London, W., July 11th.

J. H. BADCOCK.

Universities and Colleges.

UNIVERSITY OF MANCHESTER.

FROM the annual statement made by the Vice-Chancellor of the University of Manchester (Sir H. A. Miers) on the occasion of degree day on June 30th, it appears that the number of students that have withdrawn from the university during the past session to join the forces or to render national service, is approximately 64, and this, with the number who had previously withdrawn, makes a total of over 460 students, with 50 of the teaching staff and 36 of the servants of the university who are absent on military, naval, or other service, while 26 members are occupied in service at military hospitals. If to these be added the former students, there are in all about 1,700 past and present members of the university giving national service in some way; over 80 members had received distinctions for services in the army or navy. The normal activities of the university have been much curtailed both in teaching and research, and in one department the students have entirely disappeared. On the whole, however, the work has been maintained with greater success than was anticipated two years ago. The energies of the university were now either directly or indirectly wholly connected with the business of the war. Ordinary research had been abandoned, and the departments had devoted themselves to experimental and advisory work for various Government departments. Since the end of 1915 the Public Health Department had made over 60,000 examinations for the military hospitals in the Second Western Command, and special investigations had been carried out in connexion with the prevention of disease. There were now 560 men and 400 women students remaining at the university, which was less than half the usual number, and almost all of them were qualifying either as doctors, chemists, nurses, engineers, or to contribute in some way to the national service. At the beginning of the past session the total number of students was 1,028, which included 314 in the faculty of medicine, but was exclusive of those only attending evening classes. While the entry of men students had grown steadily less, there had been an increase of women students, mainly due to the remarkable increase of entries in the faculty of medicine. There were now 91 women medical students as compared with 67 in the previous session.

In alluding to the fund for the endowment of a department of Russian at the university, the Vice-Chancellor said he was now at liberty to announce that the anonymous gift of £5,000 was from Sir Wm. Mather, who had also given a further £1,000, and the original condition attached to the first gift that a further £5,000 should be obtained was now removed. The fund now stood at about £9,500, but the university needed at least £20,000 for the purpose.

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examinations indicated:

M.D.—F. C. Wilkinson.

FINAL M.B., CH.B.—*Part II*: R. A. Cooke, *S. G. Evans, *P. E. Gorst, *Phoebe A. Ince, W. A. Jackson, *G. R. James, *V. E. Jones, V. I. Levy, G. A. Mitchell, G. S. Swan, *Constance M. Tinkler, Frances Weighman, Mary H. Wild, H. G. Young. *Part III*: A. L. Davies, R. R. Evans, S. D. S. Greval, Mary E. Illingworth, W. M. Jones, Edna E. Mawson, M. B. Strock.

* Therapeutics. † Forensic Medicine and Toxicology.

UNIVERSITY OF GLASGOW.

THE following candidates have been approved at the examination indicated:

M.B., CH.B. (M., Mater. Medica and Therapeutics; P., Pathology; M.J., Medical Jurisprudence and Public Health).—J. S. Aitken, M.; C. O. Anderson, P.; J. D. Arthur, P.; A. K. Begg, M.; A. S. Bisset, P.; W. G. Burns, P.; J. Caddies, M., P.; W. J. S. Cameron, P.; T. W. Carstairs, P.; J. G. Coltart, M., P.; H. L. Coulthard, P.; A. M. Davidson, P.; *J. Donald, P.; W. Edgar, P.; M. F. Gibson, M., P.; G. O. Grant, P.; J. Hewitt, M., P.; H. J. Hollis, P.; R. G. Howat, M., P.; J. A. Jenkins, M., P.; S. H. W. Kameron, M., P.; J. Kirk, P., M.J.; A. C. Lindsay, M., P.; R. M. Courtney, P., M.J.; D. Maclean, P.; F. K. Macmillan, P.; A. W. M. Rorie, P.; R. Mair, M., P.; J. M. K. Maxton, M., P.; J. S. Meighan, P.; M. S. Molema, M., P.; J. B. Morrison, M., P.; B. F. Niblock, P.; *J. Nicol, P.; J. W. Peden, P.; J. Pollock, M., P.; J. M. Ritchie, P.; W. Scotland, M.; H. H. Spencer, P.; N. E. Stone, M., P.; J. B. Sweet, M.; J. L. Turpie, M.; J. A. Walls, P.; R. K. Watt, M., P.; R. Young, P.; S. Young, M.; Helen F. Allison, P.; Susan S. Bryce, M., P.; *Elizabeth P. Cameron, M., P.; *Mary T. L. Clark, M., P.; Emily L. Clow, M., P.; Veronica C. J. Davies, M., P.; Edith D. Dobbie, P.; Charlotte A. Douglas, M., P.; Margaret H. Grant, P.; Helen Hogg, M., P.; Alison M. Hunter, P.; Alice M'Elwee, M., P.; Alice M'Glashan, M., P.; Annie I. C. MacIardy, M.; Margaret E. MacLaren, M., P.; Mabel M. Maclean, M., P.; Caroline J. MacLennan, M., P.; Agnes H. Macwhirter, M., P.; Georgina Murdoch, M., P.; Kathleen Nicol, P.; Margaret M. Paterson, M., P.; Louisa E. Pigeon, M., P.; Helen L. Ralston, M., P.; Margaret N. Robertson, P.; Elaine B. S. Stocquart, M., P.; Muriel A. Stowe, M., P.; Jean B. Thomson, M., P.; Marion Thomson, M., P.; Helen B. Wilson, M., P.

Passed in Medical Jurisprudence and Public Health of the Fourth Professional Examination under the new medical ordinance: W. Barras, M. Chalmers, K. J. A. Gillanders, E. P. Irving, A. Kennedy, V. J. Perry, I. M. Robertson, J. J. Robertson.

* Passed with distinction.

UNIVERSITY OF ABERDEEN.

THE Duke of Richmond and Gordon was installed Chancellor of the University of Aberdeen on July 6th, and delivered an address.

The following degrees were conferred:

M.D.—J. M. Duncan, R. Richards.

M.B., CH.B.—*C. Reid (with second-class honours), J. W. Bowman, *F. W. Carter, C. A. Harvey, B. W. Jones, D. W. MacKay, Achyuta Menon Mannatazhat, A. Y. Milne, G. F. Mitchell, A. G. Reekie, J. M. Savage, J. I. Watson, C. Wood.

* Passed Fourth Professional Examination with distinction.

W. L. Yell has passed the Final Professional Examination with distinction, but will not graduate until he attains the necessary age.

The John Murray Medal and Scholarship has been awarded to G. R. McRobert as the most distinguished graduate M.B. of 1917.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE meeting of the Fellows of the College for the election of three Fellows into the Council in the vacancies occasioned by the retirement in rotation of Mr. Harrison Cripps and Mr. V. Warren Low, C.B., and by the death of Sir Frederic Eve, was held on Thursday, July 5th. The result of the poll was as follows:

Candidates.	Votes.	Plumpers
MR. VINCENT WARREN LOW, C.B.	295	38
MR. JAMES SHERREN	228	32
MR. W. HARRISON CRIPPS	220	10
MR. FRANCIS J. STEWARD	197	53
MR. H. BETHAM ROBINSON	188	15
MR. HAROLD BARR GRIMSDALE	147	28
Fleet Surgeon Percy W. Bassett-Smith, C.B.	137	13

The President declared Mr. Harrison Cripps and Mr. Low duly re-elected and Mr. James Sherren duly elected. Mr. Cripps being third on the poll becomes substitute member for the late Sir Frederic Eve until July, 1920.

633 Fellows voted; 626 by post and 7 in person.

Obituary.

ARTHUR WEBB JONES, M.D., B.S. LOND., F.R.C.S. ENG.

COLONEL A. H. TUBBY, C.M.G., A.M.S. writes:

By the untimely death of Arthur Webb Jones, the British community in Alexandria and numerous friends have sustained a great loss. Dr. Webb Jones was educated at Malvern College and St. Thomas's Hospital. He received the diploma of F.R.C.S. Eng. in 1900; not content, however, with this, he worked for the degrees of the University of London whilst engaged in active practice in Egypt, and he became B.S. in 1911 and M.D. in 1913. As the subject of his thesis for the latter degree he selected "Bilharziosis in Women," and on this question he was able to write authoritatively owing to his wide experience in gynaecological surgery in Alexandria.

For five years—1900–1904—Webb Jones served in the Egyptian army in the Sudan; and on leaving to settle in private practice in Egypt he received the official thanks of the Sirdar and Governor-General of the Sudan for his services. His merits and abilities were recognized by his appointments as medical officer for the Alexandria district, to the Egyptian State Railway, and of surgeon and gynaecologist to the Government hospital there. During the Gallipoli campaign the medical and surgical resources of Egypt were taxed to the uttermost, and Webb Jones volunteered and did yeoman service to the British troops from May, 1915, to December, 1916.

Webb Jones had not been out of Egypt since 1913, and when an epidemic of typhus fever broke out this spring in Alexandria, it found him, fatigued and somewhat out of health, though keen as ever upon his duties. He was called upon to give an intravenous injection of saline solution to a brother practitioner, dying from typhus, and accidentally inoculated himself in doing so. In about ten days the disease showed itself, and despite the assiduous and affectionate care of Colonel Sandwith, Consulting Physician E.E.F., of Captain Walker, R.A.M.C., and other friends, he succumbed on the eleventh day. His funeral was attended by representatives of every official and administrative branch with which he was or had been connected, and by very many others who desired thus to express their sorrow. Although it was not given to Webb Jones to fall fighting in the front ranks, yet it may be truly said that the manner of his death was that of one who fell with his face to the foe, for he died at the post of duty, and in the effort to save the life of a fellow medical man.

Of his abilities as a surgeon I have been given opportunities of forming an opinion. He was a sound diagnostician and a careful and skilful operator. His judgement was good and his successes notable. Looking through his notebooks we find his cases carefully recorded, and he was in the habit of adding his subsequent impressions and investigations to the account of each case, thus continually striving to perfect his knowledge and technique, and so to crystallize his experiences. As a colleague and friend, Webb Jones was most desirable, and happy were those who were admitted to his friendship. A winning manner, entirely free from any trace of self-assertion, and a sense of complete reliability which he diffused combined to render him a quiet tower of strength in trouble and illness. Had Arthur Webb Jones been permitted to reach the allotted span of life he would have gone far. He leaves a widow and a young family and numerous friends to grieve at his departure.

DR. J. T. BALLANTYNE, the senior practitioner of Darwen, Lancashire, died on June 26th at the age of 72. After studying medicine in the University of Glasgow he graduated M.B., C.M. in 1878, and first practised in Glasgow. A few years later he went to Darwen, where he practised for nearly forty years. He was a J.P., and was long a member of the Darwen town council, on which his knowledge of sanitary science was of great value. After serving some years as alderman he was unanimously elected mayor of the borough in 1898. In spite of the cares of a busy practice he found time to take a leading part in municipal affairs, and his year of office was successful. A colleague, "W. M.," writes: "Dr. Ballantyne was for many years president of the Darwen Medical Society, attending the meetings regularly, and taking a keen interest in all scientific questions. He was ever ready to further the welfare of the society, and regarded it as his special duty to promote good fellowship among the members. He had great diversity of tastes; his love of arts and music and his fondness for travel made him a delightful companion. In his public and private work he was one of the most fearless of men, and was at all times strongly opposed to any suggestion savouring of inefficiency or humbug. He could sing a good song and tell a good story, and appeared at his best when making a speech at a Darwen dinner. A huge man, with a large heart, he was always kind and sympathetic towards suffering humanity. He gave largely and unostentatiously. Darwen owes him a deep debt of gratitude for the forty years of strenuous life which he devoted to the public interest of the town of his adoption."

DR. ANDREW LEGAT died at South Shields on June 15th in his 94th year. He was educated at the University of Edinburgh, took the diploma of L.R.C.S.Edin. in 1844, and graduated M.D.Edin. in 1845. He had practised in South Shields nearly the whole of his life and only retired a few years ago. He was appointed a magistrate for South Shields in 1880 and was one of the oldest occupants of the bench. He had taken a great interest in the work of the British Medical Association and was an ex-president of the North of England Branch. In 1856 Dr. Legat wrote an account of the first case of apparent drowning treated in England by the Marshall Hall method. He also claimed to be the first medical man to give chloroform, in the North of England, for operation.

DR. JAMES THOMAS CALLCOTT, who died from heart failure recently at Invergarry, N.B., aged 68, was born in Sunderland and received his medical education at University College, London, and the University of Durham. He took the diploma of M.R.C.S.Eng. in 1874 and graduated M.B.Durh. in 1880 and M.D. in 1883. He was medical superintendent of the City Asylum, Gosforth, and had previously held the post of assistant medical officer to the Lancashire County Asylum, Whittingham, and deputy medical superintendent to the Durham County Asylum, Winterton. Dr. Callcott, who was unmarried, was a keen salmon fisher, and for several years pursued his favourite hobby while on holiday in Scotland. He was a member of the Newcastle-upon-Tyne Division of the British Medical Association.

MR. WILLIAM GEORGE TOTTENHAM POSNETT died on June 17th, aged 46. He received his medical education at the schools of the Royal College of Surgeons in Ireland and took the diploma of L.R.C.P.I. in 1893 and became a Fellow of the College of Surgeons in 1900. He held the position of surgeon to out-patients at St. Paul's Hospital for Urinary Diseases, London, and had been pathologist to the Johannesburg Hospital and in the Transvaal Government Bacteriological Laboratory. He was at Bloemfontein during the Boer war, and was one of the operators at No. 8 General Hospital, where he performed over 600 major operations. During the Zulu rebellion he held a commission as surgeon-captain. In August, 1914, he offered his services to the French Red Cross; he served at Yvetôt and received a warm letter of thanks from the French medical service. In July, 1916, he was appointed by the War Office to examine recruits. He was then in the best of health, but often spoke of the bad ventilation and insanitary state of the recruiting stations. About Christmas last he began to have rises of temperature, which he attributed to malaria. He gradually lost weight and suffered from cough and hoarseness. On March 13th tuberculous laryngitis was diagnosed and both lungs were found to be affected. Dr. Arthur Ransome, F.R.S. (Bournemouth), writes: "I have drawn the attention of the medical officers of the L.C.C. and the Local Government Board to the risks their officers are running under those conditions, and believe they have taken active steps to abate the evil. For Mr. Posnett, as my son-in-law, I had a warm affection, and early realized his great abilities as a surgeon, and this qualification, coupled with his high sense of duty, make his early death a loss to his country, as well as to those belonging to him; but if these lines should open the eyes of the authorities to the dangers to which medical men are subjected at home, as well as abroad, perhaps the sacrifice will not have been in vain."

WE have by an oversight failed to record the death of Dr. J. STEWART BOYD at Richmond on October 6th, 1916, after an illness of seven months. He was greatly missed at Custom House, Essex, where he had an extensive practice for twenty-seven years.

Medical News.

THE Minister of Pensions has appointed Colonel Sir John Collie, R.A.M.C., to be Director of Neurasthenic Institutions.

THE annual meeting of the National Association for the Prevention of Consumption will be held at 20, Hanover Square, on Monday next, at 5 o'clock, when Lieut.-Colonel G. Sims Woodhead will give an address on farm colonies for the tuberculous.

DR. C. W. SALEEBY will give a lecture on "Armoured Men" at the Royal Institute of Public Health on Wednesday next, at 4 p.m., in place of Lieut.-Colonel Monckton Copeman, whose lecture, owing to an official engagement, has been postponed until the autumn course.

ON July 5th John Henderson Bell, M.D., of Beaufort Mansions, Chelsea, convicted in the previous week of attempting to produce a disease in a sergeant of the Australian forces, was charged at Clerkenwell police court with a similar attempt in the case of Sergeant-Major Hawkins. Dr. Bell, in giving evidence on his own behalf, denied the charges. The magistrate found him guilty, and sentenced him to six months' hard labour for each of the two offences, the sentences to run concurrently. Leave to appeal was granted in both cases.

A Maternity Nursing Home at 13, Princes Gate, S.W.7, was opened by the Professional Classes War Relief Council early in 1915 for the benefit of the wives of professional men adversely affected by the war. Over three hundred babies have been born therein. Applications for admission or for assistance in regard to maternity expenses at home should be made to the secretary. We are in a position to say that the institution is well conducted and deserving of support. Probably many doctors in various parts of the country come across cases which have been hard hit by the war, and to whom such an opportunity as the institution affords of getting over the period of confinement would be a great boon.

THE special appeal tribunal appointed by the Minister of Pensions to consider appeals from invalided soldiers and sailors against decisions that their disabilities are not attributable to, or have not been aggravated by, naval or military service, has now begun to hear cases. The medical members of the tribunal are Dr. Norman Moore and Mr. Bilton Pollard.

A JOURNAL entitled *Quaderni di Medicina Legale* has lately been started in Italy. It is to appear monthly in 50-page numbers, and will deal especially with subjects of military legal medicine, malingering, and injuries and accidents among working people. It is edited by Dr. A. Cevidalli, professor of medical jurisprudence in the University of Parma, and is published at Milan (via Mascheroni, 20).

Psychobiology is the title of an American periodical which is to appear every second month. It will be devoted chiefly to the publication of the results of research in the field common to psychology and the various biological sciences, or having a distinct bearing on the biological foundations of psychology. Manuscripts intended for publication should be addressed to Professor Knight Dunlap, Johns Hopkins University, Homewood, Baltimore.

At the second Medical Congress of Venezuela, held in January, resolutions were passed inviting the Academy of Medicine to promote the fusion into a national league of hygiene the existing organizations against malaria, tuberculosis, syphilis, alcoholism, ankylostomiasis and quackery, and to appoint a permanent commission to organize and direct an investigation into the diseases of the country. It was decided to send to Sir Leonard Rogers of Calcutta "a message of admiration and gratitude" for his introduction of emetine in the treatment of dysentery and hepatic abscess. The third meeting of the congress will be held at Bolivar in 1919.

At a recent meeting of the administrative council of the Pasteur Institute, Paris, Dr. Albert Calmette, director of the Pasteur Institute at Lille, and Dr. Louis Martin, director of the Pasteur Hospital, were unanimously appointed subdirectors in the room of Dr. Chamberland and Professor Metchnikoff. Dr. Chamberland, who died in 1908, has had no successor till now. Dr. Calmette, who founded the Pasteur Institute at Saigon, has taken a leading part in the campaign against tuberculosis in France, and Dr. Martin, who has been associated with the Paris Institute since 1902, has made researches on the bacteriology of diphtheria, the prophylaxis of contagious diseases, tuberculous meningitis, tetanus, anthrax, and sleeping sickness. At the same meeting M. Vallery-Radot, Pasteur's son-in-law and biographer, was elected president of the administrative council.

A RECENT report shows that the Red Cross Advanced Stores Dépôt of the Joint War Committee of the British Red Cross and the Order of St. John has been at work at Baghdad for some time, and that there are twelve Red Cross motor launches in use. It is desired to establish a large fleet of such launches, picking up the sick and wounded along the banks, with motor ambulances to bring them to the river by the shortest route. Eighteen motor launches were dispatched from England between May 29th and the end of June, and five others are building. The hospital ship *Nabha* has rendered great service. The vessel had its own ice-making plant, and was able to turn out two tons of ice every twenty-four hours, which had been of great assistance to the hospitals. Provision is being made for a considerable number of hospitals in Baghdad, and also for an officers' convalescent hospital of fifty beds, and a convalescent camp of one thousand beds.

THE sixty-eighth annual meeting of the American Medical Association was held at New York from June 4th to 9th. The secretary reported that the membership on May 1st, 1917, was 82,501, and the number of Fellows 44,010, an increase for the year of 829. The Chairman of the Board of Trustees, Dr. W. T. Councilman, reported that the weekly average issue of the *Journal* of the Association during 1916 was 67,255. The principal item of expense in publication was that of paper, which was equal to one-third of the total expenditure; the cost of ink, rollers, wire, linotype, metal and supplies generally, together with that of labour, had increased. It was proposed to decrease the size of the *Journal*. A resolution had been passed at the February meeting of the Board that all papers read at the annual meeting should be treated as volunteer papers, and published in full or in abstract in the *Journal* or rejected as might seem best. The Chairman of the Council on Health and Public Instruction, Dr. Frank Billings, reported that the financial condition had made it necessary to abandon for the time being the programme of investigation, education, and legislation which had been followed during the past four

years. During the past year the Council had confined its efforts to the production of literature which could be supplied to State Boards of Health, educational and philanthropic bodies, women's clubs, and similar organizations. From June 1st, 1915, to May 16th, 1916, the Council printed and distributed 1,133,500 pamphlets, of which 750,000 were on minimum health requirements for rural schools; the others were on defence of research, conservation of vision, prevention of cancer, public health, sex hygiene, social insurance, care of babies, and public health measures as to venereal disease. The report stated that the Council was opposed to the use of alcohol except in the preservation of pharmaceutical preparations. It was decided that the next meeting should be held at Chicago under the presidency of Dr. Arthur Dean Bevan of that city.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology, Westrand London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisecra, Westrand London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

INCOME TAX.

H. M. S. has for many years deducted two-thirds of his rent, rates, etc., in making his income-tax return. This year the surveyor refuses to allow two-thirds but offers "one-half."

* * The statutory rule is that H. M. S. can deduct a reasonable proportion of his rent, etc., "not exceeding" two-thirds. What proportion of his yearly outlay for rent and rates is expended for professional rather than private purposes is, of course, a question of fact. Speaking generally, the professional cost would probably bear a higher proportion to the private cost in large towns, and as two-thirds is the maximum, something less is generally accepted as applicable to smaller towns. One test that may be suggested is whether or not H. M. S. would spend more than one-third of his present rent if he were a solicitor, for instance, with a separate office and an identical income. A case presenting some slight analogy is that of a clergyman, who can deduct only one-eighth of his rent for a room set aside for the purposes of his calling.

LETTERS, NOTES, ETC.

FINGER SPLINT FROM CACTUS STEM.

MR. F. D. BANA, M.B.Bomb., M.R.C.S.Eng., D.P.H.Oxon. (Bombay), writes: A trolleyman, with a painful swelling on the first interphalangeal joint of the right index finger, applied for treatment here on May 25th, 1917. He had improvised a hollow splint from the fresh stem of a cactus, having removed the soft pulpy part from the centre. The splint measures 2½ in. in length by 1 in. at one end and ¾ in. at the other in diameter. From its slightly sausage-shaped curve it fitted the index finger comfortably, following the slight convexity of the finger, which, as everybody knows, is not quite as straight as the other fingers when extended. The fresh juice of the core of the stem is often used by the natives to paint any painful swelling; it adheres as a varnish. In this case the splint served as an excellent temporary support for the finger by resting it and preventing movement of the swollen joint.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

THE CLINICAL ORGANIZATION OF THE MEDICAL PROFESSION.

AN ADDRESS TO THE METROPOLITAN COUNTIES BRANCH,

BY

C. O. HAWTHORNE, M.D.,

PRESIDENT.

[AFTER thanking the members for his election as President of the Branch, Dr. Hawthorne paid tributes to the memories of Sir Victor Horsley and Dr. Major Greenwood, and continued as follows:]

We shall at least all allow that organization is a subject which merits attention, seeing that the term has become one of the master-words of the moment and that the methods of medicine, as many other methods, are likely in an increasing degree to be tested by it. Of organization for medico-political purposes it is hardly necessary here and now to speak in commendation, for it is a motive which explains, at least in part, our present meeting. I will, however, allow myself the expression of a personal conviction that no prospect of success in this direction presents itself outside the liberal and democratic constitution of the British Medical Association. Here is a free and open platform for every advocate who has counsel to give to his fellows, and if, even as in other organizations, it is the fate of minorities to suffer, there lies ready to hand an infallible prescription by which the experiences of a minority in the Valley of Humiliation may be changed into the triumphs of a majority and the delights of the Delectable Mountains. This prescription contains but two ingredients—the one a good cause; and the other an indomitable will. Another professional field in which the principle of organization is likely in the immediate future to find an increasingly close application is that related to the care of the public health, and I fancy most members of the profession are prepared to welcome a more intimate co-operation and a more orderly co-ordination of activities which up to the present have been directed by different, and sometimes by conflicting Government Departments. "A Ministry of Health" is an inviting phrase, and provided it be translated in harmony with an enlightened medical opinion it may command operations of great benefit to the nation. In the provision of this opinion the representatives of the British Medical Association have already shown their readiness and ability to take a due and appropriate share.

But neither in medical politics nor in preventive medicine do the great majority of medical practitioners find their daily occupation and concern. We have interests in both the one and the other, but our immediate responsibility and duty is the care of sick folk. Of course, complete success in the prevention of all disease and suffering would be the greatest of medical triumphs. But such an hour is not yet, and in spite of leagues and associations and committees there is likely for many a long year to persist an active demand for the services of those who can carry a knowledge of expert medicine to the bedside of the individual sufferer. "Send for the doctor" is one of the acute cries of human need, and it lies with us to secure, so far as possible, that this cry is not uttered in vain. Now an effective response to the claim implicit in such an appeal demands obviously fullness of clinical knowledge and soundness of clinical judgement. Aid from the laboratory and kindred sources we may obtain and ought to obtain, but after all, the final word lies not with these but with the bedside student. What I wish to inquire is whether it may not be possible by some scheme of organization to do something to enlarge the store of clinical knowledge and to secure its more effective distribution in the profession.

At the outset I state two preliminary propositions: First, that the acquisition and extension of clinical knowledge implies practical, personal, bedside study; and the second, that clinical problems are so varied and, not infrequently, so involved that their full educational values are most likely to be obtained by a combination of practitioners, each of whom is willing to throw his individual experiences and his individual judgement into the common stock. My preliminary thesis, in a word, is that to further and promote clinical efficiency we must establish and extend clinical organization.

Obviously for such an organization it is necessary to provide a centre, or rather a series of centres; and my suggestion is that the natural and most appropriate centre in each individual district is the local hospital. At present, with rare exceptions, there is no regular and recognized relation between the work of the hospital and the interests and activities of those who practise medicine in its neighbourhood, and it is this state of affairs which I wish to see remedied. Therefore I urge that, instead of being, as at present, outside and detached from the hospital scheme, the local profession shall be enlisted as part and parcel of its clinical machinery; and that in connexion with each hospital shall be organized an arrangement of mutual help in the prosecution of clinical knowledge and in the promotion of clinical efficiency. The most immediate and obvious benefit of such a scheme would be a better and more complete personal knowledge of individual cases, for every one concerned would be in a position to gain a full record of the patient—his medical history prior to his admission to hospital, the events observed in hospital, and also the later developments. The arrangements in other words, would remedy, or would help to remedy, what I fancy we all admit to be one of the most serious defects in our personal clinical equipment—namely, its patchy and partial character. Art is long, and especially long is the art of clinical medicine; and it is because of this that judgement is difficult. We must unite our experiences if within the brief compass of an individual life we are to obtain anything like an adequate survey of the wide field within which lie our duties and responsibilities.

To come now to practical details. Clearly, if any movement in the direction here suggested is to be developed there must be a first step, and my submission would be that this first step ought to be taken by the hospital. The hospital has both a recognized position and an existing organization, and these confer both opportunity and responsibility; and probably at the outset not too cordial a response must be expected. Mistakes and misunderstandings have hardened and emphasized a separation which never ought to have existed, and time and tact and temper will be necessary to get rid of their effects. An initial proposal might well be the establishment of an arrangement by which any practitioner who sent a patient into hospital should be invited to meet in consultation the hospital officer under whose charge the patient was placed. Apart from other benefits, this would secure accuracy in the earlier history and the possibility of completing at a later date the patient's record; and generally it would help to establish a habit of co-operation and to develop an atmosphere of goodwill. But the hospital ought to do much more than this. It ought to organize, say on one or two days in the week, a series of clinical demonstrations or consultations to which members of the local profession should be invited, and in which they should be asked to take part. Such meetings should by no means be occupied mainly or even largely with the presentation of odd, exceptional, and peculiar cases. On the contrary, they should enclose an attempt to display the actual clinical pictures or dramas provided by the wards and the out-patient department; to consider the meaning of events or combination of events existing as facts in individual patients; and to endeavour on a co-operative basis to frame in each instance a reasoned diagnostic, prognostic, and therapeutic scheme. Details of arrangement and management would doubtless differ in different localities, and these would be readily adjusted were it once recognized that as an effective aid to the promotion of professional efficiency clinical study ought to be organized, and that the natural centre for such organization in each individual district is the local hospital.

The principle thus stated would, in addition to those above defined, find many other opportunities for expression. Personally I should place much emphasis upon the educational value of *post-mortem* examinations. These are comparatively common in hospital work but difficult to obtain in private practice, and their absence is a real defect in the practitioner's experience. Hence I would make the hospital *post-mortem* room open to the local profession, and would arrange that any practitioner who would enter his name on a list kept for the purpose should receive notice when a necropsy was to take place. There might, indeed, be instances where the scheme of organization could be more readily commenced here rather than in

the clinical department. Whether on this side or on that, a beginning means much and could not fail to issue in larger ambitions.

Again, the clinical laboratory ought to be made a centre of practical interest to the practitioner, and the ideal scheme would enable him to attend in order actually to see for himself the results of the tests applied in connexion with cases for which he was responsible. Too many of us are content in this matter to accept reports for which we can supply no personal verification, and it may perhaps be asked whether such a proceeding is capable of ethical defence, seeing that in the relation between practitioner and patient there is implied on the part of the practitioner the guarantee of a personal responsibility.

A third possibility of the establishment of an organic union between the local hospital and the neighbouring profession would be the institution of a medical reference library with obvious advantages to all concerned. There exist a number of admirable atlases illustrative of various departments of clinical work, but their expense forbids their wide distribution, and they remain of little general service. To be effective these illustrations need to be displayed, and a clinical picture gallery constructed from these and other sources, and in every hospital, would mean within reach of the majority of practitioners an attractive and stimulating centre for the diffusion of clinical knowledge. Hospitals are usually very keen, and rightly so, on the creation of a pathological museum. But the pictorial side of clinical work has little recognition paid to its educational values, and many contributions of this order, save for some special reference, remain isolated from the interests they are well fitted to serve. The creation of an opportunity for their exhibition widely throughout the profession would be an educational advance of high merit.

Such, then, are some of the developments which might be expected were it once recognized that our hospitals ought to be, not merely centres of benevolence, but also centres of organized clinical enterprise and progress in which members of the local profession would find their share, their interest, and their pride. Before such a position can be reached there must probably be an educational campaign directed both to the profession and to the lay public, and especially perhaps to those among the latter who form the governors of our hospitals. We have recently had a demonstration of what can be secured when our hospital authorities are convinced that the institutions over which they preside have large public and educational interests to serve, and no one now objects to the institution of special hospital clinics for the treatment of diseases which but yesterday were held to be outside the range both of sympathy and of help. It can hardly be doubted that a similar welcome would wait on such a scheme as is here proposed when the responsible authorities were satisfied, as they surely could be, that its adoption would mean both an increased area of hospital usefulness and a greater measure of helpfulness for the individual patient.

I now go further and say that along such lines as are here defined may be found a large contribution to a question of the highest importance—namely, the provision of ready opportunities for post-graduation medical education and study. Most of us in our younger, more flexible, and more impecunious days—that is, in the days when we most need such opportunities—cannot afford to leave our practices for a number of weeks and months to visit one or other of the great educational centres; and even at the best the necessary brevity of such visits puts an inevitable limitation on their values. If post-graduation medical education is to become effective and widely spread, it must offer itself in more sustained opportunities and must secure centres not very far away from the scene of the practitioner's daily duty. My contention is that the local hospital ought to be such a centre, and its wide and continuous service makes it all the more appropriate to this end, seeing that the aim of post-graduation study is not to tempt the practitioner to forsake the wide horizons of general practice for some narrow and restricted sphere of work, but to raise the all-round proficiency of those who are the chief agents for carrying the help of medicine into the homes and lives of the people. The benefits of such an arrangement would not be all in one direction. On the contrary, the scheme here outlined would not only make available larger and more systematized clinical opportunities to the great body of the profession, but it would exercise a helpful and stimulating pressure on our hospital

staffs. It would urge them both to raise their routine work to the highest possible level and also to equip themselves with the latest developments of clinical doctrine and practice and to be agents for the communication of these to their professional brethren. Related to this is the suggestion that all such educational schemes should include opportunities for lectures or demonstrations by those whose original work had become wedded to clinical service as well as by others who had attained a recognized position of professional leadership and authority. These ends are perhaps for the fullness of time, but an opportunity for beginnings is ready to hand and wisdom will not despise it.

SUMMARY.

To sum up my suggestions in brief form I would say: (1) That the general efficiency of the profession may be promoted by the organization of co-operative clinical study; (2) that for such organization appropriate centres already exist in the shape of our local hospitals and kindred institutions; (3) that an effective scheme of this order demands the co-ordination of the work of the hospital with the interests of the local profession; and (4) that by movement in this direction are to be secured ready, sustained, and distributed opportunities for the cultivation and development of post-graduation medical education and study.

I submit these suggestions with great respect to the attention of the Branch.

THE ANTISEPTIC PROPERTIES OF ACRIFLAVINE AND PROFLAVINE, AND BRILLIANT GREEN;

WITH SPECIAL REFERENCE TO SUITABILITY
FOR WOUND THERAPY.*

BY

C. H. BROWNING, R. GULBRANSEN,

AND

L. H. D. THORNTON.

(From the Bland-Sutton Institute of Pathology, the Middlesex Hospital.)

(A Report to the Medical Research Committee.)

IN view of the attention which has recently been directed to the employment of "flavine" compounds and other basic benzol derivatives in the treatment of infected wounds, it appears desirable that certain features of these bodies, and especially of the flavine group of antiseptics, should be dealt with in greater detail than hitherto, in order that those who intend to employ these substances clinically may have more fully at disposal the indications for their use afforded by laboratory investigations. Subsequent trials along similar lines have fully substantiated the reports already published on the use of these antiseptics, but it is not proposed at present to enter further into clinical results until continued tests on an extensive basis enable a decision to be reached as to the best mode of application and range of usefulness. The powerful bactericidal properties of acridine dyes were pointed out by Browning and Gilmour, who also investigated brilliant green and other triphenylmethane compounds.† They observed in the case of acridine compounds that, in marked contrast to most other antiseptics, their action was enhanced by the presence of serum. With the exception of carbolic acid, we do not know of any other antiseptic which is not greatly weakened in its action by admixture with serum, nor are we aware that this property has been claimed for any powerful bactericidal substance. A further study of compounds belonging to this group was undertaken with a view to determining their suitability for therapeutic use in infected wounds (Browning, Gulbransen, Kennaway,

* We have much pleasure in acknowledging our indebtedness to the Medical Research Committee for a grant toward the expenses of this work.

† These are all "elaborate compounds of which most are brilliantly coloured and are used as dyes"; such characteristics are inseparable from the compounds in question, but they have been suggested for use clinically on account of outstanding properties which are likely to render them valuable in the treatment of infected wounds—at present so urgent a problem—and which are not shared by any colourless substances thus far known.

and Thornton). The substances investigated included 3,6-diamino-acridine derivatives with substituted methyl groups in the amino side-chains, or in the benzol rings, or in both positions; also the unsubstituted 3,6-diamino-10-methyl-acridinium compound—"flavine," now called "acriflavine"—prepared by Benda for Ehrlich, and originally named "trypaflavin," on account of its therapeutic action in trypanosome infections.*

The term "flavine" compounds will continue to be applied to the acridine group of compounds as designating them in relation to their use as antiseptics. The results of clinical trials in the case of acriflavine and allied flavine bodies have been reported by Colonel Pilcher, D.S.O. (see Browning, Gulbransen, Kennaway, and Thornton, also James), and by Ligat, and Thornton and Walker from the wards of the Middlesex Hospital. Since the publication of the above work the unsubstituted 3,6-diamino-acridine sulphate ("proflavine")† has also been examined more completely than had been done in connexion with the base by Browning and Gilmour.

It was found that while, in the case of all the diamino-acridine compounds tested, the antiseptic effect was enhanced by the presence of serum, especially for *B. coli*, diamino-methyl-acridinium chloride ("acriflavine"), and diamino-acridine sulphate ("proflavine") exerted the least degree of inhibitory effect on phagocytosis.

The effect on phagocytosis was in the first instance tested according to Wright's method, whereby equal quantities of human serum, washed human "leucocyte cream," emulsion of organisms and appropriate dilutions of antiseptic were mixed together, and then incubated in capillary tubes for twenty minutes at 37° C. At the end of this time the mixtures were spread on slides, stained, and the number of organisms ingested by fifty leucocytes estimated in each case; the control contained normal saline in place of the antiseptic. The serum and corpuscles were on every occasion obtained from the same subject. The organism employed was a twenty-four hour agar slope culture of *Staphylococcus aureus* emulsified in normal saline to give an homogeneous emulsion of about two thousand million organisms per cubic centimetre; a number of antiseptics were investigated simultaneously so as to avoid attaching importance to any differences in the results due merely to individual variations.

Observations made by Colonel C. J. Bond on the effect of these substances (acriflavine and proflavine) on leucocytes *in vivo* have yielded similar results to our own.† He estimates the influence of antiseptics on leucocytes in two ways: (1) By dressing a wound with gauze soaked in the antiseptic with protection against drying; at the next dressing the leucocytes entangled in the gauze are examined in normal saline with reference to their capacity to phagocytose starch granules previously dusted on the wound. Dead leucocytes lose this property. Or the pus cells from such a wound may be incubated with carmine granules in a plasticine cell. Colonel Bond finds that in spite of slight damage leucocytes in pus from a wound irrigated or dressed with acriflavine are capable of ingesting pigment granules when incubated. (2) A drop of blood from the finger is mixed with antiseptic in saline solution and then incubated in a hermetically sealed chamber. The leucocytes which emigrate from the clot and collect on the slide are gently washed in saline and then treated with 1 per cent. iodine solution, and their capacity to give the "iodophil reaction" is so tested. Any definite degree of damage to the vitality of the leucocytes hinders the elaboration of "iodophil substances" during the period of incubation. Hence the presence of the latter may be taken as a delicate method for detecting injury to the white cells. The "iodophil reaction" was obtained to a considerable degree with acriflavine and proflavine 1:1,000 in normal saline when employed in this manner.

These compounds are comparatively little toxic for the body as a whole, and although proflavine is slightly the

more inhibitory towards phagocytosis, its general toxicity for mice, as tested by subcutaneous injection, and also the irritating effect of concentrated solutions on the conjunctiva, are markedly less than that of acriflavine. The bactericidal concentration of proflavine is practically the same as that of acriflavine—that is, for *Staphylococcus aureus* and *B. coli* in serum 1:100,000 to 1:200,000. In the case of streptococcus (*pyogenes* and *enterococcus*) and the bacillus of malignant oedema it is also equal to acriflavine. The concentration which reduces phagocytosis of *Staphylococcus aureus* to 50 per cent. of the control is 1:500 in the case of acriflavine, and proflavine is only slightly inferior in this respect. The concentration of proflavine which produces slight irritation of the conjunctiva (rabbit) is 1:50 as compared with 1:150 in the case of acriflavine when applied for three minutes. The methods of test were those previously described.

The Parts Played by Phagocytosis and Antiseptics in Overcoming Local Infection.

Recent observations of Bond, Rous and Jones, and others, suggest that organisms may be protected rather than destroyed as a consequence of being ingested by leucocytes. This may bear somewhat the same relationship to the cellular aspect of immunity which anaphylaxis does to the humoral, but in view of Metchnikoff's classical observations it is difficult to relinquish the conclusion that phagocytosis is, in general, part of an important defensive mechanism. We have extended our previous work by studying the effect of prolonged contact of a solution of antiseptic in serum on the phagocytic power of leucocytes, when subsequently staphylococci are added. The mixtures of one volume each of "leucocyte cream," serum, and antiseptic solution were incubated in capillary tubes at 37° C. for two hours. The control contained saline instead of antiseptic. At the end of this time one volume of staphylococcus suspension was added, and after thorough mixing the whole was again incubated for twenty minutes in order to permit of phagocytosis occurring. Films were then made in the usual fashion. It was found on comparing in this way the flavine compounds with mercuric chloride that 1:10,000 of the flavine antiseptics, after two hours' contact with the leucocytes at 37° C. had little effect on the phagocytic power, whereas this concentration of the mercury salt reduced the phagocytic count to below 50 per cent. of the control. Now it is to be remembered that, so far as bactericidal action is concerned, 1:10,000 represents practically the limiting concentration of mercuric chloride, any further dilution of which with serum abolishes antiseptic action; on the other hand, such highly bactericidal concentrations of the flavine antiseptics after prolonged contact leave the leucocytes still capable of phagocytic action. Accordingly, both the flavine compounds are recommended for trial in the prevention and treatment of septic infection in wounds.§

Properties Desirable in a Therapeutic Antiseptic.

The question as to what constitute the most advantageous properties of an antiseptic depends almost entirely on the particular purpose for which it is used. Thus, the sterilizing of material outside the human body, as in disinfecting garments, instruments, etc., is a matter entirely different from sterilizing a wound; in the former practically the sole necessity is to destroy the organisms, but in the latter the properties of the antiseptic must be so adjusted as to ensure efficient action on the bacteria while at the same time giving rise to a minimum of tissue destruction or interference with those protective and proliferative functions upon which healing depends. A cogent illustration of the point in question is the harmlessness of flavine compounds when solutions of 1:1,000 strength are brought into contact with the peritoneum. It appears most likely that in wounds, especially when treated early, actual destruction of the bacteria through the sole agency of the antiseptic is not essential, it being necessary merely to ensure that no significant multiplication of the implanted pathogenic organisms takes place; in other words, a concentration powerful enough merely to inhibit proliferation

* In our previous work the abbreviation "flavine" was applied to the latter compound, but since this name might give rise to confusion owing to its use in connexion with other substances in commerce, the product here referred to will in future be called "acriflavine," as suggested by the Medical Research Committee.

† The specimen of this substance required for our investigations was prepared by Drs. Burger and Ewins in the Department of Biochemistry and Pharmacology of the Medical Research Committee, and we have pleasure in expressing our indebtedness to them for the valuable facilities which were thus placed at our disposal. The name "proflavine" has been suggested to us by the Medical Research Committee. As it is in the form of a salt (sulphate) that 3,6-diamino-acridine is recommended for use the name is, therefore, to be applied to the sulphate.

‡ We are indebted to Colonel Bond for permission to record these results (see also BRITISH MEDICAL JOURNAL, July 7th, 1917).

§ Proflavine represents an earlier stage in the production of acriflavine, hence it would be cheaper in use. The solubility of proflavine is similar to that of acriflavine in normal and hypertonic NaCl solution, and along with 0.5 per cent. sodium citrate; the addition of alkali to the neutral solution must be avoided, however, in the case of proflavine, as this causes precipitation. Clinical observations indicate that proflavine has haemostatic action.

is sufficient. The efficient prophylactic effect of flavine compounds in the treatment of contaminated wounds in civil practice before suppuration had set in bears out this view. Accordingly, it is far preferable to succeed in inhibiting organisms in a wound, while at the same time avoiding damage to tissues or diminution in their resistance, than to aim at obtaining bacterial sterility by means of reagents which produce necrosis and throw out of action protective mechanisms such as phagocytosis. Although for sterilizing instruments, etc., the more rapidly an antiseptic works the better, for wounds it is equally efficacious, from the point of view of healing, to destroy the organisms in ten minutes or in ten hours, provided that their virulence is efficiently controlled.

In connexion with the use of "bacterial charts," on which Carrel relies as a criterion for basing the prognosis of behaviour in a wound destined for suture which is undergoing treatment by frequent periodic flushing with hypochlorite solution, it must be remembered that diminution in numbers of the organisms is considered in this case to be practically synonymous with loss of power to cause pathogenic action. The fact that the effects which follow inoculation with bacteria depend very largely on the size of the dose is, of course, well established; but it is also, in general, impossible to determine by microscopic inspection the virulence of a given organism. Accordingly, the evidence accumulated by the bacterial charts must be clearly understood so far to apply under a special set of circumstances. There is no proof that the standards established in connexion with hypochlorite solutions will apply precisely to wounds treated by other antiseptics. Information on this point in connexion with flavine compounds and other substances must be interpreted without bias derived from a knowledge of the significance of the findings under the particular conditions studied by Carrel.

The Rate of Progress of Sterilization.

In view of these considerations as to what an efficient therapeutic antiseptic should accomplish, it appeared unnecessary that for therapeutic purposes in wounds there need be great rapidity of the lethal action exerted by antiseptics such as the flavines, which, so far from suffering diminution in potency through admixture with serous secretions, are most active in the presence of serum, and hence must continue to act for a long period, and which, in comparison with their bactericidal potency, are relatively harmless to the tissues. Dakin and his co-workers would also seem not to regard great rapidity of action as essential in antiseptics to be used for treatment, since they adopted two hours as the duration of contact between antiseptic and organisms in their experiments. Many observers, however, following more or less the classical procedure advocated by Rideal and Walker, estimate the bactericidal value of a compound according to the effect produced by contact of the antiseptic with the organisms for a comparatively brief period—up to fifteen minutes. It is difficult to determine from the results of such short contact experiments what conclusion, if any, may be drawn regarding the action of greater dilutions acting over longer periods, as would almost necessarily be the case in wounds unless the antiseptic is immediately fixed or inactivated.

Browning and Gilmour, following the procedure of Churchman, originally tested the antiseptic power of a substance by incorporating it in melted agar medium, and then, after cooling, they inoculated the surface by stroking with a loopful of a dilute suspension of a 24-hour culture. In later work the method adopted by us was to test the power of inhibiting growth and killing the organisms in fluid medium.

The substance to be tested, in a volume usually not exceeding 0.1 c.cm., was added to small test tubes containing 1 c.cm. of the culture medium, which consisted in one series of 0.7 per cent. peptone water and in the other of undiluted serum, and then 0.1 c.cm. of a 1 : 20,000 dilution in saline of a twenty-four peptone water culture was added. A control was made with peptone water or serum without antiseptic; one loopful of this mixture when stroked immediately on agar yielded twenty or more colonies of staphylococcus or *B. coli*. The tubes were then placed at 37° C., and were examined at the end of twenty-four to forty-eight hours in order to determine the concentration of antiseptic which killed the organisms introduced; the development of turbidity, of course, indicated the occurrence of definite proliferation of the bacteria, but subcultures were made also on agar and in peptone water. The results of both methods of subculture corresponded in general; but it was sometimes found that cultures containing antiseptic, which showed no turbidity after incubation and in which, therefore, little or no multiplication of organisms had occurred, still contained living bacteria.

We selected the quantity of bacteria employed for the inoculation dose because, when added to the standard volume of fluid used in our tests (1 c.cm.), a loopful yielded a convenient number of colonies for estimating subsequent increase or decrease. The impression may arise, however, that this minute quantity was employed because the flavine antiseptics could not withstand a test involving the rigour of a larger inoculation. Hence we add the following experiment:

ESTIMATION OF BACTERICIDAL CONCENTRATION OF ACRIFLAVINE FOR *B. COLI* IN OX SERUM (57° C.).

The tests were carried out as previously described; but three parallel series were set up, which differed only in the amount of organisms used for inoculation. Of a twenty-four hour peptone water growth of *B. coli* (Escherich) each tube (1 c.cm. volume) received respectively, in Series A, 0.1 c.cm. 1 : 20,000 dilution; Series B, 0.1 c.cm. 1 : 1,000; Series C, 0.1 c.cm. undiluted culture. The mixtures were placed at 37° C. and subcultures made on agar at intervals. The controls contained no acriflavine.

TABLE I.

Time of Subculture.	Dilution of <i>B. coli</i> Culture used for Inoculation.			Controls.
	A. 1 : 20,000.	B. 1 : 1,000.	C. Undiluted.	
At once ...	(+ 1 : 100,000 — ?	1 : 10,000 ?	1 : 10,000 ?	15 colonies in loopful from Series A; ∞ from C.
2 hours ...	(+ 1 : 100,000 D — ?	1 : 40,000 D 1 : 20,000	1 : 40,000 D 1 : 10,000 D ?	No increase as compared with "at once."
5 hours ...	(+ 1 : 100,000 D — ?	1 : 100,000 D 1 : 40,000	1 : 40,000 D 1 : 20,000	Increase.
24 hours ...	(+ 1 : 400,000 D — 1 : 100,000	1 : 400,000 D 1 : 40,000	1 : 100,000 D 1 : 40,000	Increase.

+ = Growth. — = No growth. D = Decrease in number of colonies as compared with control made from same series "at once."
? = Concentration not determined.

Thus, a twenty-thousand-fold increase in the inoculating dose causes only about a two-and-a-half-fold increase in the amount of antiseptic necessary to produce sterilization.*

Experiments on the rate of progress of sterilization were carried out as an essential part of the work preliminary to our first report and the results were briefly referred to, but it appeared then to be unnecessary to enter into details on this point. It seems, however, that observers may experience some difficulty in dissociating the conception of potency of antiseptic and bactericidal action from that of rapidity of sterilization. Further, sufficient emphasis, perhaps, has not been attached to the fact that, in order to secure the best performance of the flavine antiseptics, it is essential that they should act in a serous medium. Therefore the experimental results are now published more fully—the method of the tests was that already described. The progress of sterilization has been investigated by making subcultures from the antiseptic mixtures at intervals of two, five, and twenty-four hours. The subcultures were made by inoculating a loopful of the mixture into 10 c.cm. of peptone water, and also by stroking agar and then incubating for forty-eight hours at 37° C. The following table (II) gives the results of representative experiments.

Thus, it is clear that, as compared with the other substances tested, the maximum bactericidal action of the flavine compound is developed comparatively slowly (proflavine behaves similarly), whereas mercury perchloride, chloramine-T and phenol, all exert their maximum effect within two hours and no significant change occurs subsequently. The flavine compound has by that time exerted only a restraining effect on the multiplication of organisms in the higher dilutions, which will become sterile later on: this is shown by the relative scantiness of growth when a subculture is made on agar from the tubes containing those particular concentrations. The progressive action of the flavine compound is evident both in the watery (peptone)

* Similar results were obtained with *Staphylococcus aureus*, but with the heavy inoculation distinct proliferation preceded the lethal action.

TABLE II.—Rate of Progress of Sterilization with Flavine Compounds and Other Antiseptics.

+ = Growth in subculture in peptone water. - = No growth. ? denotes that the lethal concentration was not determined.

medium and also in serum. The following graphic representations (all to the same scale) of the results in serum demonstrate strikingly the difference between the progress of sterilizing action of diamino-methyl-acridinium chloride (acriflavine) on the one hand, and mercury perchloride on the other; in this respect the mercury salt behaves similarly to the other antiseptics tested, although, of course, much higher concentrations of the others are

has been observed in the case of the allied methyl-violet compounds by various observers. Accordingly a fifteen minutes' test on the Rideal-Walker plan, especially in a watery medium with the flavine compounds, will reveal so low a "coefficient" as to discourage those who would seek to estimate the therapeutic possibilities of a substance according to this criterion.

The Importance of a Serum Medium in Intensifying the Antiseptic Action of Flavine Compounds.

The results shown by the table also illustrate exceedingly well the fact which has been repeatedly remarked upon—namely, that serum is essential in order that the full bactericidal activity of the flavine compounds should develop. This is especially true for *B. coli*, but also holds for the other organisms tested—namely, *Staphylococcus*

* Indicates actual observations. The heavy line shows lethal concentrations. The broken line shows non-lethal concentrations.

required, as shown in the table. After two hours' action the difference between the lethal concentration of mercury perchloride and of diamino-methyl-acridinium chloride is practically negligible, as we have previously noted; subsequently the effect of the flavine compound becomes at least ten to twenty times more potent than that of the mercury salt, and even a further increase in the sterilizing action has been observed to occur from the twenty-fourth to the forty-eighth hour (see table). Brilliant green (sulphate of tetra-ethyl-diamino-triphenylmethane carbinol), which was first employed in the treatment of infected wounds by Leitch,* is also slow in action, a feature which

* In our previous report the experimental basis for the conclusion that brilliant green is preferable to malachite green as a therapeutic agent, has been fully stated.

aureus, *Streptococcus pyogenes*, and *faecalis* (enterococcus), and the bacillus of malignant oedema.

Relative Bactericidal Potencies for *B. coli* (see our previous report)—

of acriflavine in water*	1
" " in serum	80
of mercuric chloride in water*	800
" " in serum	8

* Containing 0.7 per cent. peptone.

Hence, other things being equal, the most satisfactory therapeutic results are likely to be obtained from these antiseptics when the conditions of the wound dressing are so arranged that the antiseptic is acting in a serum medium.

In order to test this point further, as far as possible *in vitro*, the sterilizing action in varying concentrations of serum has been estimated, and it has been found with staphylococcus* and *B. coli* that even 25 per cent. serum causes a ten to forty-fold increase in the bactericidal action of "acriflavine" and "proflavine" as compared with the effect in 0.7 per cent. peptone water (higher amounts of peptone—that is, 5 per cent.—diminished the bactericidal power).

Investigations have not yet decided upon what factor this intensifying action of serum depends. Preliminary experiments along with E. L. Kennaway have shown that the fluid derived from boiled serum, which contained a trace of protein, on some occasions intensified the action, while other specimens lacked this effect. A specimen of human cerebro-spinal fluid containing only a trace of protein also exhibited the intensifying action on acriflavine as compared with the effect in 0.7 per cent. peptone water, and in this specimen of cerebro-spinal fluid the bactericidal effect was equal to that in undiluted serum. Thus it is possible that the flavine compounds may have an application in the treatment of cerebro spinal infections when introduced intraspinally. But it is essential that clear indications of the suitable dosage should first be obtained experimentally, since the cerebro-spinal system represents a locus in which intense and peculiar pharmacological effects occur. As regards cerebro-spinal meningitis, it has been reported that "the use of flavine by intraspinal injection has been distinctly unfavourable" (Gray); but no details of dosage are given.

Therapeutic Application of Brilliant Green.

Antiseptics which are diminished in their activity by serum ought clearly to be renewed frequently in a wound in order that a concentration lethal to the bacteria may be maintained (unless complete sterilization could be effected almost immediately by a single application!). The danger attending this procedure is, of course, the possibility of toxic action exerted by the substance on the tissues, and it is for this reason that carbolic acid and mercuric chloride, which are poisonous both locally and also after absorption, are generally avoided; on the other hand, the neutral hypochlorite solutions are rapidly converted into innocuous compounds. Among antiseptics of the type inactivated by serum, brilliant green possesses the advantage of being an extremely potent bactericide—far exceeding the flavines in watery solution—while at the same time it is comparatively harmless to phagocytosis, as well as to the tissues locally, and when applied to a wound it is devoid of general toxic action on the body.

Brilliant green 1:2,000 in water represents a bactericidal concentration for staphylococcus and *B. coli* which is respectively 500 and 7 times that of Dakin's solution; at the same time it is much less harmful to phagocytosis than is hypochlorite. Hence it might be anticipated that brilliant green would prove valuable when employed according to Carrel's approved method of intermittent irrigation at two-hourly intervals. Lieut.-Colonel Hull has applied brilliant green in this manner, and we are indebted to him for an unpublished communication to the effect that "brilliant green 1:2,000 has proved superior to Dakin's solution for use according to Carrel's method with two-hourly flushing." Brilliant green has previously been used in the form of wet dressings with very favourable results by Leitch, and also by Ligat, who, by this method, however, found flavine compounds greatly superior; it is clear from what has been already stated why this should have been Ligat's experience. Webb also considers brilliant green superior to "eusol." As regards further modes of application of brilliant green, Lieut.-Colonel Hull reports having used a 1:2,000 solution in the form of hot stipes with exceptionally good results in the case of acute septic compound fractures and amputation stumps. In burns, brilliant green 1:2,000 was also used to irrigate the burn, which was then treated by the paraffin method, the paraffin containing 1:2,000 brilliant green. This treat-

ment of burns in Colonel Hull's hands proved superior to any tried method.

Suggested Applications in Wound Treatment.

The sterilizing action of flavine compounds—acriflavine and proflavine—progresses gradually as compared with that of mercury perchloride, phenol, or chloramine-T. Thus, after two hours' contact in the presence of serum, mercuric chloride is practically equal to acriflavine in its lethal effect on staphylococcus and *B. coli*. But by this time the effective action of the mercury salt on the bacteria has come to an end, and a concentration which has then failed to kill the organisms exerts subsequently little or no inhibitory effect on the proliferation of the survivors. On the other hand, concentrations of the flavines which at this period have merely inhibited multiplication, later on prove bactericidal, so that finally the flavine compound is ten to twenty times more lethal than corrosive sublimate. Experiments show that such concentrations of flavine, while effectively controlling the bacteria, do not interfere with phagocytosis. The clinical evidence which has already been obtained indicates that when the flavine compounds are used for therapeutic purposes in the treatment or prevention of septic infection in wounds this slow progressive action is not a disadvantageous feature, since, on the one hand, the tissues are not harmed by the concentration of the antiseptic employed, and, on the other, admixture with the serous secretions of the wound enhances the sterilizing effect instead of bringing it to an end. It is therefore suggested that, in estimating the value of antiseptics for therapeutic purposes, a test such as that associated with the names of Rideal and Walker, which involves only a brief contact between antiseptic and organisms, is not likely by itself to afford satisfactory indications, although it has been found invaluable as a means of determining the relative potencies of quickly acting bactericidal agents designated for sterilizing instruments, clothes, polluted fluids, etc.

There is a clear indication that for the treatment of wounds it is advisable to avoid too frequent flushing with watery solutions of the flavine compounds.† The explanation is in all probability a twofold one. In the first place, the maximum antiseptic effect of flavine is obtained in a serous medium. Further, since the antiseptic properties—and also most probably other actions of these bodies—are not rapidly neutralized by the tissue secretions, too frequent additions of fresh doses may lead to undesirable cumulative effects on the tissues locally. This would account for unsatisfactory results following two-hourly irrigations with acriflavine solution used merely as a substitute for the approved hypochlorite. However, brilliant green has proved of great value when employed in watery solution by Carrel's approved method of frequent intermittent flushing, which is to be explained by the fact that it acts best in watery solution, and is applicable in a highly bactericidal concentration without causing harmful effects to the tissues, either locally or generally.

Should it be desired to adopt the method of introducing flavine compounds into wounds by means of tubes, in place of packing with gauze soaked in the 1:1,000 solution once or twice daily, it is suggested that the best results may be obtained by introducing small amounts of fluid, the frequency of the irrigations not exceeding three or four in the twenty-four hours. There is, however, no reason so far for suggesting that the method of irrigation will prove superior to packing adequately applied; in fact, the evidence now at disposal points definitely in the other direction. It is hardly necessary to comment on the numerous advantages which would attend a method necessitating only one or two manipulations of the patient daily.

Once the infection has been practically overcome considerably weaker solutions of flavine bodies than 1:1,000—for example, 1:5,000—may be subsequently employed with advantage, or in late stages the application of flavine may be intermitted for a day every few days, dry dressing being substituted in the intervals, or one may use "stimulating" applications such as Leitch first demonstrated brilliant green (1:1,000) to be. Since individual variations in the behaviour of the tissues of different patients must

* For some unascertained reason the bactericidal potency of flavine compounds for staphylococcus in dilute peptone water shows considerable variations in an extended series of experiments, whereas with serum the results are remarkably constant, hence the "lift up" due to the serum is caused to vary.

† We are indebted to Dr. Carrel for a preliminary account of observations on this point in the case of acriflavine.

play an important part in the process of healing it is important to discover at this stage what compound will secure the best progress.*

Prevention of Sepsis.

Special attention is directed to two further points—first, the possibility of preventing sepsis by the use of flavine compounds in early wounds at a period before the evidence of infection has developed. It may be doubted whether it is advisable to practise immediate suture of war wounds in the fashion which has been so successful in civil practice after thorough surgical cleansing and pouring in as much acriflavine 1:1,000 as the tissues will contain; possibly an interval of some days should be allowed before suturing, and if success follows this procedure the time may be shortened. It may be noted here that there is every indication that proflavine will be at least as harmless to the tissues as acriflavine when injected subcutaneously and between muscle planes.† Secondly, attention is directed to the promising results which have attended the use of flavine compounds with the purpose of preventing recrudescence of acute septic manifestations when operating in an area already infected, for example, in secondary amputations.

The Importance of Preliminary Operative Procedure.

It must be emphasized again that the usual surgical procedures are an essential preliminary to the use of flavine or brilliant green, in order that these antiseptics may be enabled to act effectively. As we have stated in our previous communication in connexion with the necessity for procedures which shall combat or prevent septic infection, "there is a great measure of agreement that the removal of dead tissue and the conversion of the wounded area into a free surface by incision and excision are essential factors"; and, again, in relation to the prophylactic application of flavine, "of course such treatment is to be used in addition to operative procedures." No quantity of flavine bodies, nor of any other feasible antiseptic so far available, seems likely to prove efficacious when there is failure to remove considerable portions of necrotic tissue or foreign bodies. Intimate contact of the antiseptic with the infected tissue must be secured.‡ The fact should not be overlooked that in our first publication we expressly emphasized such considerations. On the other hand, it would require the greatest optimist to assert that operative procedures in themselves achieve all that could be desired in the treatment of infected wounds. Thus, there is little doubt that the appropriate employment of efficient therapeutic antiseptics, combined with operative measures, can effect an almost incalculable saving; such benefit will be especially evident if the antiseptics may be applied simply and quickly.

It has been the purpose of our work thus far to examine certain little-known antiseptics, like brilliant green, or substances like the flavine bodies, whose almost unique characters as potent bactericides do not seem even to have been suspected. Laboratory tests as well as clinical trials have demonstrated, *inter alia*, that these compounds are devoid of harmful side-actions which might prejudice their use. Accordingly, we venture to urge most strongly their employment on an extensive scale, as we believe that their outstanding properties can be utilized practically to great advantage, and will lead to general recognition of the fact that they constitute a notable addition to the treatment of infected wounds and other accessible localized infective lesions. Work is in progress with a view to the development of substances suited for special uses, and it is hoped that further advance may be effected if those interested in special clinical aspects will formulate the requirements which they desiderate in substances to be employed for their particular purposes.

SUMMARY.

1. Flavine compounds and brilliant green are antiseptics which exert a slowly progressive bactericidal action.

* In certain cases the prolonged application of flavine dressings to the skin has caused the appearance of a vesicular eruption, which has rapidly disappeared on interrupting the treatment.

† The absorption of flavine compounds is followed by an appearance of green fluorescence in the urine, but no toxic action has been found to result therefrom. Observations on intravenous injection will be recorded elsewhere.

‡ Several clinical observers have applied flavine compounds incorporated in a paste with a view to securing "dépôt" action (see Bond, BRITISH MEDICAL JOURNAL, July 7th, 1917).

Concentrations of these substances which at first inhibit and finally kill bacteria, are without harmful effect on phagocytosis or on the tissues locally or generally; hence they are specially suited for therapeutic purposes in infected wounds. Flavine compounds may be applied to the peritoneum with safety.

2. Flavine compounds (acriflavine and proflavine) are enhanced in their bactericidal potency by the presence of serum; brilliant green, in common with most other antiseptics, is reduced in its activity by serum.

3. The most suitable method of application of an antiseptic for therapeutic purposes must depend very greatly on its behaviour in the presence of serum. When the antiseptic is inactivated by serum, frequent renewal of the watery solution is indicated as in Carrel's procedure; this, of course, is only permissible provided that the substance is not in itself toxic.

4. Brilliant green satisfies the requirements for application by repeated irrigation, as a powerfully bactericidal solution (1:2,000) in water is practically innocuous to the tissues. On the other hand, since flavine compounds are most bactericidal in serum, the indication is to arrange the wound dressing so that these antiseptics may act in a serum medium; also, since these bodies are not rapidly thrown out of action by serum accumulative deposit should be prevented by avoiding too frequent additions of considerable quantities of the antiseptic solution. Clinical experiences have substantiated these conclusions, and the evidence at disposal points to the application of flavine bodies by means of gauze packing or some appropriate modification of this procedure as likely to yield the best results. Thus there is evidence that, by taking full advantage of the properties of flavine bodies, a relatively simple technique may be followed.

5. The application of the flavine compounds especially for the purpose of preventing the onset of septic manifestations in early wounds is emphasized; also their use for preventing exacerbations after operating in areas already infected.

6. Operative measures are an essential preliminary to the effective use of therapeutic antiseptics in wounds, since the antiseptic can act only when brought into intimate contact with the infected tissues.

MEDICAL AND SURGICAL NOTES FROM MESOPOTAMIA.

BY

G. GREY TURNER, MAJOR R.A.M.C.(T.).

PART II.

HEAT-STROKE.

THE cases coming under the heading "Effects of Heat," though interesting, were depressing and disappointing, for so very often treatment was unavailing. I shall not soon forget the streams of patients in June and July who were hurried to the bath house, nor the occasion when nearly a dozen stertorous patients lay in the open air along the side of the creek, many of whom went to make up the sixteen funerals that left our hospital the next day. These men were not weaklings, but often big strong fellows who might be expected to be the last to go under. Nearly every case illustrated the importance of prophylaxis and of early treatment, and those that developed in hospital often recovered as the result of prompt measures to reduce the temperature. But the heat regulating centres are so much deranged that relapses are common, and there can be no

* Part I was published on July 14th, page 53.

doubt that anybody who has suffered from a severe attack should be sent out of the country. *Post-mortem* examination in these cases was disappointing, the appearances were not uniform or characteristic and there was much less cerebral or meningeal mischief (to the naked eye) than we expected. The congestion of the internal viscera which we always found was, I am sure, only a consequence of the slow process of dying from coma. There is a great deal of work to be done on these cases, and until their minute pathology and chemico-pathology is better understood the methods of treatment must be empirical and haphazard. Prophylaxis is the most important thing, and the responsibility for the transport and care of troops coming fresh to a moist hot climate like Basra in May, June, and July, must always be great. Every detail must be attended to, and the soldiers must be tended like ignorant children, and no point is too small or trivial to be neglected.

As a result of conversations with men who had suffered from the effects of heat in its various forms, I am satisfied that those who tolerate heat badly at home should not be sent to this climate. New troops, and especially their officers, coming to tropical countries should be educated as to the precautions necessary. New-comers revel in the sun and suffer; they should be taught that the sun is an enemy to be avoided, that the head and back of the neck should be covered, and that advantage should be taken of every little bit of shade. But it takes some time before one instinctively walks at a funereal pace and seeks the most trivial of shades. Men should never leave camp without their water-bottles, and every care should be taken to avoid exhaustion.

JAUNDICE.

In May and June many men suffered from jaundice, and one medical officer in charge of 62 beds had as many as 25 cases under his care at one time. I doubt if this jaundice was really of the epidemic type, and we all thought that at least some of the cases were malarial in origin. Many different factors were probably at work, but in the absence of adequate laboratory facilities at that time we were unable to examine them by blood culture, etc. Two cases died, and at the *post-mortem* examination I found all the appearances which we associate with delayed chloroform poisoning, and which must have been the result of some profound toxæmia. In another case, a coloured subject, my colleague, Lieutenant F. G. Thomson, found catarrhal pancreatitis, but in that instance the symptoms were largely abdominal pain and distress.

Being interested in the question of infection of the gall bladder, I examined many of the cases with this in view. In several the liver was enlarged and tender, and in a smaller proportion the tenderness was limited to the region of the gall bladder, but there was no case of cholecystitis requiring operation, though, as will be mentioned later, I had several of the latter following enteric group infections.

DYSENTERY.

The dysenteries formed a large proportion of the medical cases admitted. The bacillary varieties were the more common, but the amoebic variety occurred also, and for them emetine is almost specific; indeed, if it fails, it suggests either a mixed infection or that the diagnosis must be revised. I had an admirable illustration of its value in the case of a patient who was admitted to hospital for the closure of an appendicostomy, which I did by removing the remains of the appendix. This man told me that he developed dysentery in India and in this state went on leave to England, where he was medically treated for some weeks without benefit. He then consulted a surgeon, who arranged a series of treatments by ionization. After eight applications he was no better, and was taken into a nursing home, where appendicostomy was performed. He remained in the home for a month, living only on light diet, and having daily irrigations of the bowel. While following this regimen he was very well and had no symptoms of dysentery, but as soon as he went out and began to take ordinary food and exercise all his troubles returned, and he passed large quantities of blood and mucus. He then went to a practitioner with a large experience of tropical medicine, who prescribed emetine. At the end of a month he was perfectly well and had never had any recurrence in spite of hard campaigning both in France and Mesopotamia. In the bacillary variety the effect of the antidyenteric serum

is often very remarkable, but if it is going to be successful it produces its good effects promptly. Many of the cases that reached us were too far advanced for treatment by this means, and in October we had quite an epidemic of fatal cases. In a few patients I tried appendicostomy without success, but one very severe case made an excellent recovery as the result of caecostomy. This operation combines all the advantages of appendicostomy without any of the disadvantages and disappointments, and if the patient recovers the subsequent operation for closure is a small matter in comparison with the benefit derived.

Liver Abscess.

The classical complication of liver abscess is far from common considering the large amount of dysentery, but I saw over a dozen cases. Three were discovered in the *post-mortem* room, and in all of these the final cause of death was rupture of the abscess into the peritoneal cavity. Others were merely suspected and cleared up under treatment by emetine; seven cases required operation for drainage. In all the interesting feature was the absence of any history or symptoms of well-developed dysentery, and in at least two there was no history of bowel trouble whatever.

The classical descriptions must have been founded on old-standing cases, for as a rule most of the symptoms described are absent. Pyrexia with slight local pain and tenderness on pressure over the right hypochondrium with slight enlargement of the liver upwards have been the suggestive symptoms, the diagnosis being confirmed by the elevation and immobility of the right wing of the diaphragm as demonstrated by x-ray examination and made absolute with the exploring needle. All my cases were treated by open incision and drainage through a lower intercostal space, the diaphragm being stitched to the parietes before being incised. In the one case that died after operation there were multiple abscesses in the liver, with empyema and pericarditis. The amoeba was never found in the pus evacuated at the time of operation, but was usually demonstrated about the fourth day. A course of emetine (one grain daily for a week) was always given after operation. In no class of case was the co-operation of physician and surgeon more helpful, and in nearly all my patients I was indebted to my medical colleague Lieutenant F. G. Thomson for valuable help in diagnosis.

Other Surgical Complications.

Other surgical complications of dysentery were perforation of the colon and acute peritonitis without perforation. In one of the cases of the former complication an inflammatory mass formed in the right iliac region simulating an appendix abscess. There was a large slough in the caecal wall with localized peritonitis, and though the appendix contained a dysenteric ulcer it was not the cause of the symptoms. I also saw cases of local thickening of the pelvic colon following dysentery, and on two occasions the condition very closely simulated a new growth in the bowel. Several of the chronic cases developed symptoms suggestive of appendicitis, and I was once or twice led to operate only to find a normal appendix. These patients may have definite attacks of abdominal pain, but the history and the diffuse tenderness over the caecum and ascending colon, and often over the sigmoid as well, enabled a diagnosis to be made.

BERI-BERI.

We had one or two cases of "beri-beri," and any number of men suffering from so-called "debility." These were to me a most interesting group, for, as I have already said, I am sure the debility of active service is some type of nutritional disease probably allied both to scurvy and beri-beri.

"P.U.O."

A diagnosis of "P.U.O." (pyrexia of uncertain origin) used to be very frequently made, but it became less and less so as the facilities for laboratory investigation increased, a large number of the cases turning out to be enteric group infections.

PAROTITIS.

When I first arrived at Amara in July I was astonished at the large number of cases of parotitis under treatment in the wards; I have certainly seen many more than I

have previously met with in the whole of my experience. I have notes of twenty-three of these cases, but many occurred when I was occupied with administrative duties and was not able to find the time to record them. The type is quite different from what one is accustomed to see at home, for they nearly all suppurate early, and form abscesses which discharge abundantly. In one patient there was enormous destruction of the tissues overlying the parotid, giving an appearance very like cancerum oris. Many of the earlier cases proved fatal, but I believe the primary disease was the real cause of death. At first I was inclined to think that the infection might be specific, but though Captain Stevenson, I.M.S., kindly examined several specimens of the pus for me he only found a coccal infection. Probably the organisms gain access to the gland along the duct, and the only common factors were that the patients had almost without exception been under treatment for some disease requiring milk diet, and that no special attention had been paid to the hygiene of the mouth. They nearly all came from field ambulances where there were no nurses, and just at a time (July and August) when the vitality of every one was at its lowest ebb, and the personnel of those units was taxed to the utmost. But even with scrupulous attention to the mouth this complication did arise among patients under treatment in our own hospital, but with, I think, two exceptions it was only in cases in the later stages of exhaustion from typhoid or dysentery.

When the cases came under my observation the proof of infection of the duct was usually evident, but whether *post* or *propter* I am unable to say. The papilla was reddened, and quite often pus could be squeezed from it, and sometimes in abundance. At a later stage the normal flow of saliva was absent, only a little thick glairy mucus being obtained on pressure. The destruction of the gland was very widespread, and it would be interesting to know what the ultimate effect on the salivary function will be. The abscesses often burst spontaneously into the external auditory meatus, or pointed near the angle of the jaw. In some of the slighter cases the question of mumps cropped up, but there has really been nothing to support the suggestion, for the swelling is usually unilateral, and nearly all suppurated; there has never been orchitis, and the condition has never spread among the other patients in the ward. As showing the care necessary in opening these abscesses, and the importance of employing Hilton's method, I may refer to a case which had previously been operated upon, and which was admitted to our hospital with complete facial paralysis. As he said, before the operation he could not open his eye because of the swelling of the face, but since he had never been able to close it. Though I never saw facial paralysis as a complication of the condition, it developed in one of my patients some days after the evacuation of pus. In this case the onset of the parotitis was preceded by herpes of the area of the fifth nerve on the same side. The paralysis was clearing up when the man was evacuated down the line three weeks after the incisions had been made.

The following is a summary of the cases of which I have notes. The series does not represent the true mortality, because, as I have said, some of the worst cases occurred at a time when I was not able to keep records:

Parotitis.

Total number of cases	23
Primary disease:				
Enteric group infections	16
Dysentery	3
Jaundice	1
Pyrexia of unknown origin	1
Nephritis	1
Parotitis	1

Four cases did not suppurate, and all recovered; 19 cases suppurated, and of these 4 died. Of the 23 cases, 11 affected the left side, 6 the right, and 6 were double.

GALL BLADDER INFECTIONS.

The most interesting complications were the gall bladder infections, and they were not at all uncommon. The cases that came to operation were particularly interesting, because they supplied a clue to those that did not require surgical interference, and because in them it was possible to establish the identity of the infecting organism. I operated on six cases. In two the gall bladder condition was frankly a complication of an enteric

infection on the down grade. In one the enteric infection had presumably occurred three months previously; during convalescence there were attacks of colic followed by a distended gall bladder, and numerous gall stones were found in the acutely inflamed viscus. In the other three cases the gall bladder infection and the enteric were concurrent. In four of the cases paratyphoid A organisms were obtained in pure culture from the bile, in one the organism was not quite typical, but was probably of this nature, and in the remaining case it was not possible to have a bacteriological examination made. All the cases recovered as the result of drainage.

The cases I saw in which an operation was not necessary usually came on some weeks or months after an illness that might be interpreted as an enteric group infection. They had acute attacks of pain followed by marked tenderness over the gall bladder and sometimes palpable enlargement. But they were not very ill, and the attacks grew less frequent and less severe, so that I did not consider it necessary to operate. The future will show whether these infections are followed by the formation of gall stones in such a proportion as to suggest a causal relationship.

RENAL COLIC.

As the weather began to get cooler we had several cases of renal colic, and though they very closely simulated calculus, in no single instance was I able to demonstrate a stone. In all the cases there was an excess of oxalate crystals in the urine, and I believe that the irritation caused by the passage of these crystals down the ureter was the correct explanation of the symptoms. When on the right side appendicitis was very closely simulated, and the diagnosis was often a matter of anxiety. An abnormally slow pulse, and the fact that the rigidity was strictly limited to the middle line, together with deep tenderness over the kidney, were all in favour of ureteric origin. At the early stage, when the diagnosis was in question, there were no urinary symptoms, and beyond the presence of oxalate crystals urinary examination did not give much help. At a later stage a trace of albumin, with large numbers of hyaline casts and a few blood and pus cells, established the diagnosis. Most cases cleared up quickly, but some were not free from pain for several weeks. A mild infection arising in this way probably explained the several cases of perinephritic abscess which also cropped up about this time.

In one case a paratyphoid infection of the kidney began so acutely as to simulate appendicitis, and it was probably an oxaluria which determined the site of infection in this instance.

THE WOUNDED.

Until the middle of December, when we began to get some wounded, the surgical cases had only represented a very small proportion of the total admissions.

I saw something of the wounded from the Kut relief force in April of 1916, but after the gallant garrison had to surrender at the end of that month the stream of wounded ceased. All through the summer months there were occasional casualties due to snipers, the attentions of Arab marauders, and to the accidents which always attend an army in the field. In December the wounded were of the ordinary types. Taken as a whole the wounds were not seriously infected, though there were occasional exceptions, but I never saw a case of tetanus nor of gas gangrene, and even in the hot weather, when resistance was at its lowest ebb, the accidental wounds healed remarkably well. Apart from recent wounds there have been a few relic bullets to be removed, and I am more impressed than ever with the wisdom of extracting missiles when it can be done without running unjustifiable risks. The cases I speak of all illustrated the importance of general methods of examination, for I was able to find the bullets and cut down on them with precision, relying on clinical signs only. They had previously escaped the surgeon's knife because the estimate of their depth by x-ray methods was supposed to have shown them in inaccessible positions. An x-ray apparatus without an expert in charge is not much use, for anything but extremely accurate localization is worse than useless. Our unit was fortunate in having Captain McCabe Dallas in charge of this department. Talking of x-rays reminds me to mention the need of other diagnostic instruments, such as cystoscopes, sigmoidoscopes, etc., which in a big station are almost as necessary as at home.

OPERATIONS OF ELECTION.

At Basra I did several operations of election for herniae, hydrocele, interval appendicitis, haemorrhoids, etc., and two very typical cases of torn cartilage, but as the weather got hotter I had to give it up because the patients so frequently developed jaundice, or malaria, or enteric group infections, or some trouble during convalescence more serious than the original disability. At Amara, with better climatic conditions, I again operated on any case that called for interference; all operation wounds healed perfectly. My only anxiety was the dust, which finds its way into everything, and I was afraid would spread the sort of minor infection which I had found to be so prevalent. However, I took the precaution of using my instruments out of antiseptic, and of having a carbolic towel near the operation area, and relying on mops used directly out of a solution of mercury perchloride 1 in 4,000, and this technique proved most efficient. Emergencies and minor surgery had, of course, always to be dealt with, and I had a few cases of acute appendicitis, but never a ruptured ulcer or strangulated hernia. It is rather surprising that there were so very few dislocations and fractures, for we drew our sick from some thousands of troops.

ANAESTHETICS.

At first we used nothing but chloroform, and although the patients took a good deal, or appeared to do so, for there was probably a lot of evaporation from the mask, they went under its influence most quietly, and there was practically none of the struggling we so commonly see at home. I am sure that this is due to the absence of alcohol and the very moderate use of tobacco—in fact, the only patient who did struggle hard was under arrest for drunkenness, a very rare crime where alcohol is not easily obtained. After a death from delayed chloroform poisoning, I threw tradition to the winds, and used ether with the greatest success. With a room temperature of 110° F. we found it answered splendidly, even when given by the open method; certainly a lot of ether was consumed, but the Ormsby or the Clover were equally successful and very little more extravagant than when used at home. At Amara we used nitrous oxide, which is the greatest possible convenience. Infiltration anaesthesia and spinal anaesthesia are both very useful, and the former I have frequently employed.

DENTAL CASES.

Among soldiers septic teeth and their complications cause a great deal of misery, as well as no inconsiderable disability, and I am satisfied that every hospital should have at least one dentist for every 1,000 beds. There is always a lot of extracting to do, but so many teeth can be saved by simple stoppings, and dentists can do so much to allay discomfort and lessen disability by the repair of dentures, etc., that their services are highly important. One general hospital had a dentist on the staff with a proper outfit and two mechanics, and in a very short time the department proved itself invaluable.

EYES.

Surgeons with ophthalmic experience are also indispensable in every general hospital, or even nearer the front if communications are long, because there are so many questions which may involve the sight of one or both eyes that can only be decided by those with special training.

THROAT, NOSE, AND EAR.

In the field of throat, nose, and ear surgery there is certainly less need for experts, but someone in each station that could be called upon in a consultative capacity is most useful. Impaction of cerumen, furunculosis of the auditory meatus, and trouble from old running ears were all common. The two former can easily be dealt with, and in my opinion the latter need not unfit a man for military service. Much can be done to relieve an old otitis, and even if not suitable for the fighting line there are many opportunities for employing such men at the base. At our hospital at Amara the "permanent base men" proved themselves invaluable as general duty orderlies at a time when our own staff was very much depleted by illness.

MILITARY SERVICE AFTER OPERATION.

I saw many cases illustrating active service after operations, and I am glad to be able to give the lie to those pessimists who state that our military hospitals are crowded with men who have been unsuccessfully operated upon for hernia, hydrocele, varicose veins, etc. Of course there are recurrences, and also men who complain as bitterly of their scars as of their original disability, but these are the exceptions. I was long enough at the hospital to see many of the patients on whom I had operated return wounded and without any complaint about the result of their previous operation. And it is the same out here; and, on the whole, I am surprised that men can undergo so much after even quite serious operations.

CONCLUSION.

The medical side of the hospital was always well employed, and, indeed, the campaign has furnished great opportunities for physicians. It has also shown the need for most liberal laboratory accommodation, and a first-rate pathologist with a good staff could be fully and profitably employed at every hospital.

We have followed the admirable plan of making *post-mortem* examinations whenever possible, and in all doubtful cases. I have usually made the examinations myself, and am able to say that if anything they are less unpleasant than similar investigations at home. Of course we make them as soon after death as possible, usually only a few hours, and never longer than twelve. Six in the morning is the best time, but I have often had to do them at three in the afternoon, and even with the thermometer at 110° and higher they have "not been too bad," to use a common service expression.

To many of us the life of the army is repellent, and will provide a great incentive to the promotion of something like a lasting peace. But from the medical point of view there are some compensations, and the war will at least have taught many men the great advantage of an unstinted appeal to laboratories and x-ray departments, and also the advantage of the very free consultations which can always be had for the asking in military hospitals. These lessons will not be lost, and must have an effect on civilian practice after the war.

On the whole, both patients and staff have kept very cheerful. There were a few cases of suicidal cut-throat, but always in men who were exceedingly ill. The hospitals are very nice, and the wards being light, airy, and cheerful the patients are very well off, though it would be ridiculous to say that they have all the luxuries which they enjoy in France or at home; yet at Christmas it would have been difficult to detect any difference. They are all glad to get into such comfortable quarters after their experiences at the front. The nursing orderlies are very good, and have worked splendidly, but the addition of sisters to the personnel has been a great advantage in every way; they greatly add to the welfare and comfort of the patients, and relieve the responsibilities of the medical officers. In the hot weather the great difficulty was to provide adequate change and recreation, both for patients and personnel. The services of regimental bands were available from September onwards at Amara, and were not only much appreciated but of great help in keeping men interested and amused. Pianos and gramophones were also very useful in relieving the monotony, and the concert parties which toured the stations during the autumn were most enjoyable. At all times the Y.M.C.A. provided entertainment and change, and every one acknowledged the extreme value of their services.

I must not forget to mention the great psychological value of the mail day. Baths and bathing are useful agents, provided they are taken at the proper time of day. Fishing can be indulged in towards evening, and provides relaxation for its devotees. Officers fond of shooting could always get sand grouse and often partridge, and there are duck and snipe, though further afield. Others enjoyed polo, and horse exercise was very popular.

From October to the end of December the evenings were cool enough for active games, and tennis, cricket, football, and hockey were indulged in and greatly appreciated after the long hot season.

The Amara Clinical Society was a great success. The idea originated with Lieut.-Colonel S.F. St. D. Green when A.D.M.S. Our first meeting was mainly devoted to the

subject of scurvy, a series of cases among Indians being shown by Major Connor and Captain Kamat, I.M.S. Subsequent meetings were held fortnightly, when subjects such as enteric, dysentery, wound treatment, and secondary haemorrhage were discussed, and at other meetings cases and specimens were shown. Weekly inter-hospital clinics between an Indian general hospital and a British general hospital were also held and were of mutual help, especially in the direction of keeping up the interest of medical officers.

I would plead for the establishment of schools for officers at all medical reinforcement camps, so that not only may the time of waiting be usefully employed, but the overwhelming monotony relieved. In this connexion I would like to add my testimony to the excellence of the Sanitary Museum at Makina. Similar museums for the exhibition of the newer splints and surgical appliances might be started at the big bases and be combined with a reference library of the literature of the war.

I am much indebted to Colonel W. H. Starr and Lieut.-Colonel H. J. Bond for the facilities afforded to me and for the invariable interest which they took in my work.

A CASE OF ACHOLURIC JAUNDICE.

BY

W. H. McKINSTRY, M.B., D.P.H.,

TEMPORARY CAPTAIN R.A.M.C.,

BACTERIOLOGIST AND PATHOLOGIST, QUEEN ALEXANDRA
MILITARY HOSPITAL.

On April 25th, 1917, the following case was sent to Queen Alexandra Military Hospital. The patient had been seen previously by Surgeon-Colonel Culver James, H.A.C., who, not being satisfied with the diagnosis (spleno-medullary leukaemia), referred him to the laboratory for an examination of his blood.

A preliminary examination of a blood film was sufficient to dissociate the patient's condition from spleno-medullary leukaemia, so he was admitted into Queen Alexandra Military Hospital, and placed under the care of Captain H. J. S. Morton, R.A.M.C., to whom I am indebted for the following notes of his history and condition, together with the notes from the patient's mother.

The patient, Pte. —, complains of no definite symptoms. He states that "as long as he can remember" he has noticed that "the whites of his eyes have occasionally been yellow." Almost ever since he joined the army he has noticed shortness of breath, palpitation and pain over the heart on exertion, and stitch in the side. These symptoms were slight, and he paid no attention to them. Fourteen weeks ago, during an inspection in France, the medical officer noticed that he was "jaundiced," and he was sent to hospital, where he has remained. He had never reported sick, and complains of nothing now. He states that he is much yellower some days than others, and that it was only discovered seven weeks ago that his spleen was enlarged.

Past History.—He was ill when 8 years old with "abdominal trouble and jaundice." Since then he has been very healthy. He had never been abroad except to France (one week).

Family History.—Father and mother both suffer from heart trouble. Brothers and sisters healthy, except youngest brother, who suffers from anaemia and weakness. No other member of the family has ever suffered from jaundice.

Present Condition.—The patient is a healthy well-made boy, 22 years of age; skin lemon tint; conjunctivae yellow with distinct jaundice, especially around the periphery. No pyrexia; tongue clean; digestion and appetite good. No haematemesis or bleeding from the gums.

Heart and Chest. Normal; pulse 80; slight pulsation of carotids and subclavians.

Abdomen. Liver felt two inches below the costal margin; edge palpable, but not hard. Spleen very large, hard, and firm. Dullness on left side of chest behind from the eighth rib downwards in the scapular line, and continuous with the splenic dullness.

There is slight enlargement of glands in the groin, but no other glands appear to be enlarged. Teeth very good, no foci of suppuration discovered; no digestive troubles; no stigmata of congenital syphilis. There is a definite jaundice tint on the soft palate.

April 30th, 1917. Jaundice of conjunctivae not so marked to-day.

The patient's mother supplied the following interesting facts (I quote her own words):

Between the age of 3 and 4 years my son (the patient) had a very bad attack of jaundice, which lasted for three weeks or longer, and for which he was attended by a medical man. Not being satisfied with the doctor attending, another doctor was

called in and he found him to be suffering from a growth on the spleen. He was taken to the local hospital and detained five months. He came out of hospital in fairly good health, but two years after he had another attack of jaundice, and has had it on and off ever since. I have another son, aged 13 years, who is also yellow. I have also a little girl, aged 11 years, who is delicate and bloodless. I have had one miscarriage, and my husband is now in hospital suffering from blood poisoning resulting from ulcerated legs. This is the fourth time he has been in hospital for this disease.

From this history and from the weak positive Wassermann return of the patient's serum I think we are safe in concluding that there is a strong syphilitic taint.

Examination of the Patient's Blood.

There was marked microcytosis and anisocytosis. These two characteristics were so striking at the preliminary examination made when first seen as to at once call attention to his urine and conjunctivae. Polychromasia, poikilocytosis, and punctate basophilia were also present, together with a few microblasts. No myelocytes were found.

Total count:

Red blood corpuscles ... 5,600,000 per c.mm.
White blood corpuscles ... 5,000 "

Differential count:

Polymorphs ... 65 per cent.
Large lymphocytes ... 20 "
Small lymphocytes ... 8 "
Hyalines... ... 6 "
Basophiles ... 1 "
Haemoglobin ... 65 "

The blood serum was decidedly yellow, and gave an indefinite reaction for bile with strong fuming nitric acid. The serum was not haemolytic to the red cells of another patient.

The fragility of the red cells was tested with different strengths of salt solution, and at the same time controlled by blood taken from the laboratory orderly. The result is appended:

Saline Solution.	Patient's Blood.	Orderly's Blood.
1 per cent. ...	No haemolysis	No haemolysis.
0.9 " ...	Partial haemolysis	No haemolysis.
0.8 " ...	Total haemolysis	No haemolysis.
0.7 " ...	Total haemolysis	No haemolysis.
0.6 " ...	Total haemolysis	No haemolysis.
0.5, 0.4, and 0.3 per cent.	Total haemolysis	No haemolysis.
0.2 per cent. ...	Total haemolysis	Slight haemolysis.
0.1 " ...	Total haemolysis	Total haemolysis.

A Wassermann test gave a weak positive reaction.

Urine.—Examined on several occasions, it was at no time high coloured, nor could any bile be detected chemically. When examined by the spectroscope, the characteristic absorption band of urobilin was seen at the junction of the green and blue.

Faeces.—Dark brown in colour, and free from blood.

Many cases of acholuric jaundice have been recorded since Mikowski in 1903 accurately described the condition. Clinically they may feature hypertrophic biliary cirrhosis, splenic anaemia, Banti's disease, Addison's disease, or congenital syphilis with enlargement of the spleen and liver, but the characteristic blood changes of the former are said to be sufficiently definite to differentiate them. In making a diagnosis it is well to keep in mind one or two points—namely:

1. The blood serum of the above mentioned diseases may contain bile.

2. Marked enlargement of the liver has been noted in cases of acholuric jaundice. In most cases, however, very little permanent enlargement is found.

3. The urine, although usually free from bile in acholuric jaundice, is on certain occasions, particularly when the jaundice is more pronounced than usual, distinctly bile coloured.

Nowadays there is a tendency among clinicians to divide cases of acholuric jaundice into familial and acquired, and in the latter group syphilis appears to be a potent factor. Whether it produces the characteristic

blood and visceral changes (and I see no reason why it should not), or whether it acts like any other debilitating agent and simply predisposes the patient to the action of other toxin or toxins, is at present undetermined.

Whatever the cause of the disease may be, it appears as if some toxin acting on the spleen causes destruction of the red blood cells with the liberation of haemoglobin, from which the liver by increased activity elaborates bile pigment, usually in sufficient amount to stain the skin and conjunctivae, but, as a rule, not enough for it to gain access to the urine; while the bone marrow is stimulated to increased production of red blood cells, which, owing to the demands made by the system, arrive in the circulation ill-formed and immature.

I wish to record my thanks to Surgeon-General Dallas Edge, C.B., for permission to publish the case, and to Captain H. J. S. Morton, M.B., R.A.M.C., for supplying me with the clinical notes.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

DERMATITIS FROM HANDLING GERMAN BOMBS.

A CASE of dermatitis from handling a German bomb which fell in the air raid on June 13th has lately been attending the skin clinic at Charing Cross Hospital. The patient was a Royal Naval gunner who was detailed by the Admiralty to the extremely dangerous work of removing the detonator from an unexploded bomb which had crashed through a house in the East End of London and buried itself 7 ft. deep in loose earth in the basement. He had to dig away the earth in the dark and, on reaching the bomb, to unscrew and remove the fuse. In so doing the loose powder from the exploder fell on his hands, and it was to this that he rightly attributed the dermatitis.

The dermatitis did not appear till about eight days after he had handled the bomb. When I saw him a few days later the palms of his hands were stained yellow as if by picric acid, the hands were swollen, inflamed, and oedematous, the skin felt hot and tense, and there were deep-seated vesicles between the fingers and on the dorsum similar to those of dysidrotic eczema. The state of the hands recalled the dermatitis from T.N.T. powder, of which a number of cases in munition workers have lately been under treatment at the clinic. The condition took about a fortnight to cure under soothing applications, such as calamine liniment followed by a zinc paste, and when I saw him on July 9th the skin had practically returned to normal. He informed me that should he be detailed for further work of this kind he will be protected by rubber gloves, which will be all the more necessary as the attack will probably render his skin hypersensitive for some time to come to the action of the explosive powder and irritants of an allied nature.

J. M. H. MACLEOD, M.D., F.R.C.P.,
Physician for Diseases of the Skin, Charing Cross Hospital.

HAVING had several cases of dermatitis from the bombed area in the City, I should like to add a few notes to supplement those of my cousin, Dr. J. H. Sequeira, and others. In the majority of cases the vesicles appeared on the ninth day. One case, however, of severe dermatitis of both hands, which I showed at the New London Dermatological Society, did not present any eruption till the fourteenth day after the patient had dug out of the earth an unexploded bomb, which, in so doing, he handled a good deal. The long interval in this case is probably to be accounted for by the bomb not having exploded. The dermatitis set up was similar to the T.N.T. cases of munition workers, in which the period of incubation after contact with the powder does not seem so definitely timed, but is determined more by the cutaneous irritability of the individual skin. The sago-grain vesicles on the fingers due to contact with bombs dropped may, it seems, appear as early as the third day, as occurred in one of my cases. A gentleman had gone into a building in the City shortly after a bomb exploded on July 7th. He felt the contact with "the powerful fumes" at the time. On July 10th he noticed the small lumps on his fingers and felt his

face was swollen. When I saw him two days later he had the usual vesicles on his fingers and an erythematous dermatitis of his face. About the same time I saw two other gentlemen from the same bombed area who also had erythematous dermatitis of the face, but no vesicles on their hands or fingers. Another patient, in addition to bullae on his hands, presented curious linear bullous lesions on his forearms, as if the localization and character had been determined by the patient having scratched that part with contaminated fingers. In only one of the cases I saw was there suppuration, and that was in a young girl from Hoxton, with an extensive bullous eruption of the left foot, which developed on the ninth day after perambulating in the debris. Her left boot had a large hole in the sole, through which the irritant penetrated and set up the mischief. Her right shoe was less defective and her right foot thus escaped damage. These cases seem to me to substantiate Dr. J. J. Pringle's remark, quoted by Dr. Adamson (p. 46).

G. W. SEQUEIRA, M.R.C.S. Eng., etc.,
London, E.C. Western Skin Hospital.

TREATMENT OF WOUNDS WITH BISMUTH IODOFORM PARAFFIN PASTE.

IN this note I wish to point out the great advantage of the bismuth iodoform paraffin paste, or B.I.P., advocated by Professor Morison and employed by him at the Northumberland War Hospital.

The following is the method of treatment which I now adopt in bony injuries, whether recent or chronic, for it is bony injuries in which this treatment gives particularly successful results compared with other methods.

First, the wound edges are excised, if this has not previously been done. Secondly, a free incision is made and loose fragments of bone and foreign bodies are removed. Thirdly, the wound is well dried with gauze. Fourthly, methylated spirit is swabbed over the wound, and, finally, with the wound as dry as possible, B.I.P. is well rubbed into the surface; a teaspoonful is usually sufficient. The wound is then lightly packed with dry gauze, and dry gauze is placed over the surface.

The following day I usually change the surface gauze, as there may be a little oozing. Then, provided the gauze packing keeps dry, it can be left in for at least a week.

If it becomes very moist with discharge I take it out and mop up the discharge with a dry swab (in contradistinction to bathing it with a wet solution), and then repack it occasionally, gradually allowing the wound to close up.

I do not intend to discuss the pathology, as this has been done by Dr. L. G. Anderson,¹ but there are a few points to which I should like to call attention.

Firstly, the reason I emphasize keeping wet dressings away from the wound is because these leave a fluid residue which wets the gauze packing, and is thus apt to give a false impression of the amount of discharge; it also washes out some of the B.I.P.

Secondly, I consider that forcible syringing of deep wounds, especially if they are not carefully dried afterwards, is a very common cause of pocketing and spread of infection along the lines of least resistance. If B.I.P. is used as described above, I feel sure that many secondary operations for establishing drainage will be averted.

Finally, in cases undergoing this treatment, an enormous amount of redressing on the boats, trains, and in hospitals would be avoided, resulting in a great economy of dressings (almost 50 per cent.) and of time and labour for the hard-worked nursing staffs. In addition to this, the patient himself will benefit and much appreciate being dressed once a week instead of daily or oftener, as the process is usually painful and very fatiguing to an already exhausted person.

E. H. WALKER, M.B., B.S. Lond., M.R.C.S.,
Captain R.A.M.C. (T.C.),
Surgeon, York Place Hospital, Brighton.

SMALL-SPORED RINGWORM OF THE SCALP IN AN ADULT.

WE are in the habit of telling people that they need not fear contagion of the ringworm fungus after the age of 15 years.

Mrs. B., aged 61, was sent to me by Dr. Llewellyn, of Bath, a few weeks ago with a rather large oval patch on the side of the scalp. Some children with tinea tonsurans had stayed with this lady and had used her brushes. I

¹ *Lancet*, March 3rd, 1917.

extracted some of the "stumps" and asked Professor Walker Hall to examine them. He reported that the majority of the hairs contained the *Microsporon audouini*.

In the Section of Dermatology of the Royal Society of Medicine on January 18th, 1917, Dr. Graham Little showed a case and said he had never met with a previous example of ringworm of the scalp in an adult. In the discussion Dr. MacLeod said that in all his experience at Charing Cross Hospital and the Victoria Hospital for children he had only seen one instance of *Microsporon audouini* affecting the adult scalp. The President (Dr. J. H. Stowers) said he thought it more than probable that instances are overlooked owing to an erroneous impression existing that this disease is limited to childhood.

Clifton, Bristol.

HENRY WALDO, M.D., M.R.C.P.

Reports of Societies.

SHELL SHOCK.

At a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland, on May 11th, Dr. F. C. PURSER read a paper on shell shock. He grouped the cases met with in this country into three classes: (1) Shell shock proper; (2) traumatic neurosis; (3) mental alienation. The symptoms of the first class were: (a) Headache; (b) insomnia; (c) dizziness, probably mental confusion; (d) tachycardia; (e) tremor; (f) general mental and physical depression. Most cases recovered fairly well with rest, warmth, quiet, and occupation. Other symptoms which made the outlook less favourable were: (a) loss of memory; (b) mental confusion; (c) epileptiform attack; (d) *petit mal*; (e) profuse sweating. The President, Dr. H. C. DRURY, said that "family stock" was an important factor in these cases. It must be concluded that the shell shock cases had less stable nervous systems than normal persons. Dr. CRAIG said that in the cases he had seen symptoms developed six weeks or so after some shock—for instance, being partially buried. Sensory phenomena were curiously uncommon, except retinal hyperaesthesia. Officers frequently exhibited some of the symptoms of exophthalmic goitre. With regard to treatment, he had not much faith in suggestion, but had found ionization often useful. Colonel CLARKE considered twitching of the face an important sign. Sweating was very marked. Many of the cases were miners in civil life, and might therefore exhibit nystagmus due to their previous occupation. Captain LAW frequently found accidental burial the exciting cause. He considered "suggestion" useless, and recommended quiet surroundings. Sir J. W. MOORE commented on the tendency to relapse. Dr. CRAWFORD thought brain concussion largely accountable. His own experience of shell fire resembled the effects of a kick on the head. Dr. PURSER, in reply, agreed that in ordinary cases sensory symptoms did not occur, but in more severe they did. As regards treatment, the men ought to be employed, but kept out of touch with war matters. He still had some faith in suggestion.

Reviews.

THE INTERNAL SECRETIONS.

THE work on this subject by Professor E. GLEY has been translated into English by Dr. MAURICE FISHBERG, and published in New York under the title, *The Internal Secretions: Their Physiology and Application to Pathology*.¹ After a brief historical sketch of how this doctrine of internal secretions developed, he defines the endocrine glands as those presenting cells with characteristic granular elements in close relation to the efferent vessels of the organ, the venous blood of which must have the physiological action and the properties of a specific substance. Many of the organs, however, which are included among the endocrine glands do not satisfy all these postulates.

¹ *The Internal Secretions: Their Physiology and Application to Pathology*. By E. Gley, M.D., Member of the Academy of Medicine of Paris, etc. Translated from the French, and edited by Maurice Fishberg, M.D. New York: Paul B. Hoeber, 1917. (Cr. 8vo, pp. 241, 2 dollars.)

But several of them, nevertheless, belong to that category by virtue of certain facts connected with them. The spleen and the thymus are examples of such organs. Neither is histologically or embryologically a glandular organ, yet they discharge into the blood products akin to internal secretions. In addition to the methods of studying the products of internal secretions by an analysis of the blood from certain organs, and by physiological experiments, there is another and a simpler—in fact so simple that it has turned experimenters from the rational path of investigating the physiological properties of the venous blood to the administration of organic extracts. That method, however, though not absolutely defective, is incomplete and inadequate. For there is *a priori* no proof that the substances present in the extract existed in the living glandular tissue; that the substances present in the living gland are regularly excreted into the venous blood of the gland; and that there is a conglomeration of substances which is evidently not discharged at random or continuously into the venous blood of the organ, but that at certain times when required for special purposes one definite substance, the sole product of secretion, passes into the venous blood. Upon such narrow basis the practice of opotherapy has been introduced, and Professor Gley utters many warnings against the hypotheses that are too liberally formulated, and against the risks of acting upon them.

OPHTHALMOLOGY.

THE last volume of *Transactions of the Ophthalmological Society of the United Kingdom*² was published before the lamented death of the president, Mr. Walter Jessop, whose presidential address on some ophthalmic lessons of the war forms the opening chapter. Succeeding chapters include full reports of discussions on the treatment of syphilitic eye affections by the newer methods, and on foreign bodies in the eye and orbit; the latter dealing for the most part with civilian injuries, but not exclusively so. A later meeting was given up to communications on injuries of the eye, at which a paper by Professor F. De Lapersonne was read, and Major J. F. Cunningham contributed notes on war injuries of the eye and orbit in cases seen at the Boulogne base since April, 1915. Captain M. H. Whiting also read a note on concussion changes in the crystalline lens observed in the present war, and Mr. Jameson Evans discussed the peripheral lesions of shell concussion. Mr. Treacher Collins discussed very fully the subject of concussion hypotony. Subsequent discussions were held on diseases of the eyelids and orbit, diseases of the cornea, diseases of the uveal tract, diseases of the optic nerve and retina, and diseases of the lens—all adequately reported in the present volume of *Transactions*, and the valuable report of the subcommittee of the society on detachment of the retina is printed in full. To the section on diseases of the nervous system Dr. S. A. Kinnier Wilson contributes a paper on dysmetropsia, a term which he proposes to substitute for "dysmetropia" to signify disturbance in the visual appreciation of the measure or size of objects, whether by over- or under-estimation. This account of the pathogenesis of a symptom to which attention has not often been drawn is of interest to the neurologist and to the ophthalmic surgeon. The volume ends with the report of council, in which it is announced that Sir George Berry will deliver the Bowman lecture this year.

Dr. WILBRAND of Hamburg, who is an authority upon the relation between diseases of the eye and nervous system, published shortly before the war a volume of lectures³ in which he maintained that it is impossible to construct a complete theory of the act of sight by the consideration of the physiology and anatomy of the organs of sight, without amplifying the knowledge thus gained with facts obtained clinically and in the pathological laboratory. In these lectures he seeks to combine pathological with physiological facts, and to furnish his hearers with a complete theory of vision. Commencing with the functions of the eye, he passes back along the optic tracts to the visual cortex, examining in turn the functions of each part of

² *Transactions of the Ophthalmological Society of the United Kingdom*. Vol. XXXVI. London: J. and A. Churchill, 1916. (Demy 8vo, pp. 533; illustrated, 12s. 6d. net.)

³ *Die Theorie des Sehens*. Von Dr. Wilbrand. Wiesbaden: Verlag J. F. Berman, 1915. (Sup. roy. 8vo, pp. 51; 2 plates, 10 figures. 1s. 9d.)

the visual apparatus. We are thus furnished with a very complete theory, but it is no more than a theory. The time at his disposal was no doubt insufficient to give the known facts upon which he founded much of his hypothesis, but he is somewhat dogmatic, and many of his opinions stated as facts have but a slender foundation. It is perhaps impossible to give elementary lectures in a limited time without dogmatism. Some of Wilbrand's views upon the nervous control of dark adaptation and the secretion of the visual purple have already been opposed by Stargardt, who had at his command cases in which war injuries had severed the sympathetic nerve. Stargardt came to the conclusion that the secretion of the visual purple was not under the control of the nervous system. There is much experimental work which tends to disprove Wilbrand's theory of dark adaptation. The book is interesting, and if the theories are taken as largely speculative it may be read with profit.

NOTES ON BOOKS.

DR. A. J. ROSANOFF has translated and re-edited Dr. ROQUES DE FURSAC'S *Manual of Psychiatry*,⁴ and has produced a tolerably short and well-arranged account of the subject that should be of service to students and medical practitioners in search of a somewhat abstract but scientific account of mental disease. It is divided into two parts. The first deals with general psychiatry, and contains chapters on the etiology and symptoms of

⁴ *Manual of Psychiatry*. By J. Roques de Fursac, M.D., and A. J. Rosanoff, M.D. Fourth edition, revised and enlarged. New York: J. Wiley and Sons, Inc.: London: Chapman and Hall, Ltd. 1916. (Post 8vo, pp. 533; 14 figures. 10s. 6d. net.)

insanity, and on the general practice of psychiatry. The second part gives accounts of the special forms of insanity: Kraepelin's classification of mental disorders is followed more or less closely. The text is clearly written, and is enriched by examples and statistics taken from both French and American sources.

*The World's Wonder Stories for Boys and Girls*⁵ has been written by Mr. A. G. WHITE to explain the universe to children who will ask questions. Here the reader will find set out the why, how, when, and where of the world at large, the evolution of life, religion, morality, and science. The author writes clearly, in a simple style, and does his best to supply rational answers to the many questions he raises. The volume should be full of interest to those for whom it is written, and should prove but little misleading to their immature intelligences. And it contains little to which a modern teacher would be likely to object.

MISS LAVINIA DOCK, in a small work entitled *Hygiene and Morality*,⁶ has expanded a paper presented eight years ago to the international congress of nurses in London. It is addressed to nurses and women social workers, and its theme is the social significance of venereal disease and the part which women should take in the crusade against prostitution. The book is an earnest, well-written, and well-informed plea for a higher standard of morality.

⁵ *The World's Wonder Stories for Boys and Girls*. By A. G. Whyte. London: Watts and Co. 1916. (Cr. 8vo, pp. 285; 40 illustrations.)

⁶ *Hygiene and Morality: A Manual for Nurses and Others, giving an Outline of the Medical, Social, and Legal Aspects of the Venereal Diseases*. By L. L. Dock. New York and London: G. P. Putnam's Sons. 1917. (Cr. 8vo, pp. 204. 5s. net.)

MEDICAL AND SURGICAL APPLIANCES.

A Portable High-frequency Apparatus.

A FORM of high-frequency generator has been introduced which has the special merit of small compass and portability. The lighting current of the usual range, either alternating or direct, is used and transformed through a small generator into current of high potential and of the necessary rapidity of oscillation. To the generator is attached an electric cable, with a handle into which is inserted a glass vacuum applicator, and by this means the violet rays (effluve) or the sparks are brought to bear upon the particular surface or passage of the body which it is desired to treat. The applicators are made in a large number of different forms. When pressed against the skin the radiant applicator gives rise to no painful sensations. It is produced by the Sterling Corporation (Great Britain), Limited, of 16, Wigmore Street, London, W. 1.

MEDICINAL AND DIETETIC PREPARATIONS.

Touraine and Anjou White Wines.

IT was not without reason that the rich and the great of the renaissance in France built their chateaux in Anjou and Touraine and chose sites on the Loire or one of its tributaries. These districts have been called, not without good cause, the garden of France, escaping the chills of the north and the torrid summer of the south. They have many vineyards and their wines have qualities which commend them to the judicious. Some of them resemble hocks, but the ordinary run have usually more character than the ordinary run of German wines, and the finest need not fear comparison with the finest of the German. Since the stocks of many German wines in this country must now be getting very low, it is obvious that the

present is a particularly favourable time for the introduction of French wines corresponding to those types of German wines which have hitherto been most popular in England. Messrs. Alex. Wood, Campbell, and Co., 62, Crutched Friars, E.C., are accordingly taking advantage of the opportunity to introduce a considerable number of varieties of the white wines produced in Anjou and Touraine as substitutes for German wines of the hock and moselle type; they have forwarded to us eight samples of these for examination, which we have analysed, with the results given in the table below.

The figures in the table indicate that the samples are natural unadulterated wines. As regards the still wines, the analytical figures for the first four samples given in the table are very similar to the corresponding average values for hock and moselle; the average acidity is perhaps slightly higher than that for the German wines, but the difference is not sufficient to be of consequence. The fifth sample, Fleur de Touraine, differs from the others merely by containing a small amount of reducing sugar and a slightly higher percentage of alcohol. The acidity of two of the samples of sparkling wines is quite low, while one contains a low percentage of sugar for a wine of this type.

The proportions of sulphate calculated as potassium sulphate show that none of the wines have been "plastered," while the total sulphurous acid in the case of the still wines falls well within the limits which are considered quite permissible, and is very small in the case of the sparkling wines; no other preservative could be detected. All the samples can fairly be described as of excellent and delicate flavour, the sparkling wines being, in our opinion, particularly good in this respect.

Name of Wine.	Specific Gravity at 15.5° C.	Alcohol by Volume per Cent.	Grams per 100 c.cm.			Rotation in 100 mm. Tube.	Reducing Sugar.	Grams per 100 c.cm.			
			Total Acid as Tartaric Acid.	Volatile Acid as Acetic Acid.	Extract.			Sulphate as Potassium Sulphate.	Total Sulphurous Acid (SO ₂)	Total Tartaric Acid.	Ash.

THE MESOPOTAMIA COMMISSION.

[Fourth Notice.]

THE INDIAN MEDICAL SERVICE.

THE Parliamentary Mesopotamia Commission is very severe upon the system of military administration in India, which it describes as "cumbersome and inept." In its relation to medical matters the position is complicated by the interlocking of the duties of the Director-General of the Indian Medical Service, and of the Director of Medical Services in India who has medical charge of the armies, both Indian and British, in peace and at war. Both posts may be held by the same officer, but, with the exception of a short period in 1916, during which Sir Pardey Lukis held both, have never been so held.

The Director-General of the Indian Medical Service is essentially a civil surgeon-general; practically his duties in relation to military arrangements in the field are confined to calling up the military medical reserve from civil employment on the demand of the military medical authorities, and supplying the drugs and certain parts of the equipment they ask for. He has to see that the medical store depôts in India are kept full and to appoint medical storekeepers. These store depôts supply the civil hospitals in India, but must also be prepared to meet any military emergency. The personnel he must supply in response to the demand of the military are officers of the Indian Medical Service drawn from civil employment, and the war reserve of military assistant surgeons and sub-assistant surgeons; he must also take measures to recruit civil medical men for military work, and must keep up the cadres of the Indian Medical Service, of military assistant surgeons and of sub-assistant surgeons.

The Director of Medical Services, India, who, with the brief interval mentioned, has always been a senior officer of the British Army Medical Service (R.A.M.C.), is directly responsible for the Army Bearer Corps, consisting of Indians of all casts, except sweepers, and the Army Hospital Corps for station hospitals for British troops, made up of sweepers, cooks, dhobis (laundrymen), and bhists (water carriers). The divisional medical stores and medical stores for station and regimental hospitals he obtains from the Director-General, Indian Medical Service. The ambulance tongas, hospital clothing, petty supplies, and menials for mobilized hospitals, Indian troops, he obtains from the supply and transport department. His tentage he must get from the ordnance, and furniture from the military works department. These complicated arrangements do not seem to be ideal, but are part and parcel of the mould into which military medical matters were cast during the Napoleonic wars. The theory is that the Army Medical Service is responsible only for the supply of personnel (medical officers, nurses, and orderlies), drugs, instruments, and dressings. As shown above, the matter in India is further complicated because the D.M.S., India, must draw drugs and certain equipment through the D.G., I.M.S.

Sir Pardey Lukis, D.G., I.M.S.

The specific references to the Indian Medical Service in the report of the Parliamentary Commission are not numerous, although its officers are included in the praise given to the executive medical officers for their zeal and devotion to duty.

The references to Colonel Hehir and Lieut.-Colonel Carter were mentioned last week; the other Indian medical officer referred to is Surgeon-General Sir Pardey Lukis, Director-General of the Indian Medical Service, who was appointed Director of Medical Service when Surgeon-General MacNeece, A.M.S., left India, and held the post for a short time until, "in accordance with the unwritten law that forbids a surgeon-general of the I.M.S. to serve as D.M.S., India, Surgeon-General O'Donnell (A.M.S.) arrived to take his place." The references to Sir Pardey Lukis in the report of the Parliamentary Commission are as follows:

Sir Pardey Lukis's term of office was one of energy—much additional hospital accommodation was provided, convalescent sections were established both for British and Indian troops, sixteen stationary sets of x-ray apparatus were ordered for military hospitals in India, the provision hitherto being confined to mobile sets, five of which were now released for use in Mesopotamia; electric light and fans were ordered for several hospitals, and the status of embarkation medical officers at

Bombay and Karachi was improved. Final sanction was received for the increase of the Army Bearer Corps from 9,500 to 14,000. The Government of India was asked for the first time to purchase motor ambulance cars, instead of relying, as hitherto, on private donors.

Meanwhile, with an eye to things actually in Mesopotamia, additional staffs were dispatched for river hospital steamers, active steps were taken to send increased apparatus for water sterilization; a special "Mesopotamian" diet for British troops was drawn up and approved; additional river hospital steamers and barges were ordered from home; designs were prepared for ambulance trains on the railways in Mesopotamia then being constructed; additional hospitals were asked for and dispatched.

Altogether, the energy displayed and the speed with which new proposals were carried through compares well with previous conditions.

In the next paragraph the Parliamentary Commission praises the energy of Surgeon-General Treherne, A.M.S., who succeeded Surgeon-General Hathaway, A.M.S., and the work of the Army Sanitary Committee sent out by the War Office to Mesopotamia, adding that "sanitation and the prevention of disease are now properly organized, and appliances of all kinds are being continually improved, as better transport facilities on the Tigris distribute the necessary machinery and apparatus."

Lieut.-Colonel R. M. Carter, I.M.S.

A private letter, which bore internal evidence of being a private letter, addressed by Sir Victor Horsley eleven days before his death to Major (now Lieut.-Colonel) Carter, was published in the *Weekly Dispatch* for July 8th. In the next issue of that paper (July 15th) the following apology appeared:

We desire to state that the letter which appeared in last Sunday's *Weekly Dispatch* from the late Sir Victor Horsley, relating to the Mesopotamia scandal, was published without the consent or knowledge of Major (now Lieut.-Colonel) Carter, to whom it was addressed.

In making this explanation, which is due to Lieut.-Colonel Carter, we also wish to point out that the letter contained several orthographical inaccuracies (such as the misspelling of names of places in Mesopotamia) which were made in transcribing the original document.

HEALTH OF MUNITION WORKERS.

(Continued from p. 50.)

VENTILATION.

The object of ventilation is twofold: (1) the removal of foul, exhausted, or polluted air, and (2) the supply of fresh air in its place—that is, air pure and clean to breathe, and an atmosphere stimulating and refreshing. Air entirely pure from the chemical point of view may afford an atmosphere of a most depressing character highly detrimental to physical efficiency.

The impurities liable to be added to the air inside the workshop are:

1. *Carbonic acid*, given off in the breath of human beings and by fires, gas lights, or any other form of open combustion. The increase in the amount of carbonic acid is accompanied by a parallel diminution in the oxygen of the air. The chemical changes produced in this way are not perceptible by the senses and there is no reason to suppose that they are, even under the most defective systems of ventilation to be found in factories, in any substantial degree harmful in themselves. Since, however, they are capable of easy and accurate measurement they are recognized as a useful index of the prevalence of more harmful impurities. It should not be assumed that a low percentage of CO₂ necessarily indicates a satisfactory atmosphere.

2. *Various ill-defined volatile substances* arising from human beings, from the skin and the alimentary canal, especially when personal cleanliness is absent and sweating is profuse. The sum of these conditions gives the familiar "smell of humanity"; the substances are probably harmless in themselves, but they excite a feeling detrimental to comfort and efficiency.

3. *Bacteria*.—Apart from the question of tuberculosis there is no doubt that the common catarrhal conditions (colds, sore throats, "influenza") are for the most part spread from an infected individual to his neighbours by organisms which are carried in the expired air with droplets of moisture, especially during coughing and sneezing, though also during ordinary breathing and speaking; though these diseases are often regarded as

trivial in character, it appears likely that if any correct estimate of loss of time and diminished output owing to "colds" could be obtained, they would prove to be the most important source of industrial inefficiency.

4. *Dust and Fumes.*—Some of the most common of these impurities are injurious because they are unpleasant, for example, the smell of hot oil, of various varnishes and the like. Others are directly harmful, for example, fumes from stoves, smoke, dust, etc.; and a further kind are of the nature of poisons, for example, fumes of lead, of brass, or of tetrachlorethane.

Relaxing and Stimulating Atmospheres.

It would be a mistake to suppose that a workshop with a large cubic capacity in relation to the number of work-people and the kind of process in operation does not require any definite ventilation, for in large shops there is a mass of stagnant atmosphere which is depressing and relaxing, and fails to provide the stimulating effect of cool air in gentle motion. This exhilarating influence of atmosphere depends essentially upon the cooling of the skin by moving air, and it is necessarily closely connected with questions of temperature and heating. Damp warm air is more relaxing than dry air at the same temperature; and the relaxing effect of a warm, damp atmosphere is much reduced if moving air is brought to play on the body; change of skin temperature is one of the essential features of a fresh, pleasant air. These considerations are fully borne out by direct experimentation in the laboratory, and the desirable atmosphere is characterized by being: (a) Cool rather than hot; (b) dry rather than damp; (c) diverse in its temperature in different parts, and at different times, rather than uniform and monotonous; and (which is intimately connected with this diversity) moving rather than still. The explanation of the familiar advantages of such an atmosphere lies in the cooling and varying stimulation of the skin of the exposed parts of the body.

Local Exhaust Ventilation.

For certain operations it is necessary to provide localized exhaust ventilation. The essentials are a duct along which a flow of air is maintained in a definite direction, and an opening or openings in the duct through which sufficient air is admitted to allow the flow to be maintained. This air carries with it dust, heated fumes such as arise from melting scrap lead, and volatile vapours such as are evolved when dope varnish evaporates. Where a keen draught, as for the removal of dust, is required, pressure fans are employed; where large volumes of air are to be removed volume fans are more economical, but care must be taken to see that the ducts are not constricted at any point, and that the total area of the openings is greater than that of the fan. Heated fumes may usually be removed without using mechanical power, but the duct must be vertical, of ample diameter and height, opening below into a bell-mouthed hood and surrounded above by a suitable wind cowl.

HEATING.

The heating of workshops in a variable climate presents great difficulties. Conditions at different times of the day and varying circumstances of use and occupation all require consideration. The ideal method is by radiant heat; rather old-fashioned stoves scattered about a shop may give good results, while the excellent and invigorating conditions which prevail in many smithies and forges are easily recognized. Gas-heated radiators, in which burnt gas escapes into the shop, are not permissible, and the plan by which warmed air is pumped into the shop—commonly known as the "plenum system"—tends to create a relaxing and depressing atmosphere and affords a striking example of how chemically pure air may, by its uniformity and monotony, constitute an atmosphere in which good work is hardly possible. The ventilation and heating of each shop, or group of shops, should be in the hands of some responsible person, but the workers must co-operate. Particularly is it important to attend to the ventilation of shops in which women are employed, since they are specially susceptible to the effects of defective ventilation.

STIMULATING ATMOSPHERE.

Whether a workshop has a satisfactory stimulating atmosphere may generally be judged by the sensations, especially on first entering from the outside air. The ordinary thermometer measures the temperature of the air; the wet bulb thermometer determines the humidity,

and gives an important measure of the facility with which the body can be cooled by sweating. These instruments, however, give only very imperfect data as to the cooling and skin-stimulating properties of any atmosphere, and it is necessary to have in addition some measure of the rate at which a warm body will lose heat. This has been investigated by Professor Leonard Hill by means of the "kata-thermometer." It consists of a large bulbed spirit thermometer (of standard size); this is heated in hot water, and the rate of cooling measured by taking the time which the meniscus takes to drop from 100° F. to 95° F., while the instrument is suspended in the atmosphere. This gives the dry reading, and shows the rate of cooling due to radiation and convection. To take the wet reading the bulb of the kata-thermometer is covered with a damp muslin glove and the operation repeated, giving the rate of cooling when evaporation is added to radiation and convection. The difference between the two readings gives the rate of cooling by evaporation. The rate of cooling at body temperature is recorded by means of a factor (determined for each kata-thermometer) in mille calories per square centimetre per second. The number of seconds occupied in the fall from 100° to 95° is divided into the factor.

Readings of the wet and dry bulb thermometer taken at the same time show how with the same wet and dry bulb readings the rate of cooling may be strikingly different. The kata-thermometer, like the human body, notes the rate of change, while the thermometer notes a given state, or the result of change. Thus the kata-thermometer takes count of the movement of the air and indicates conditions of comfort.

The following examples illustrate the results obtained. A comparison of the first, second, and third sets of readings shows that with the same temperature widely different rates of cooling may exist:

	Temperature.		Rate of Cooling at Body Temperature in Mille Calories per sq. cm. per sec.		
	Wet Bulb.	Dry Bulb.	By Radiation, Convection, Evaporation.	By Radiation, Convection.	By Evaporation.
1. Bright, pleasant day in May, out of doors	60	68	27.2	7.5	19.7
2. Brass foundry (good)	60	72	24	7.3	16.7
3. Machine shop (bad)	61	72	15	4.6	10.7
4. Cartridge annealing and cleaning (bad)	64.5	80.5	17.5	3.0	14.5
5. Cartridge annealing and cleaning (good)	54.5	60	24	9.0	15.0

LIGHTING.

The essentials of good lighting are:

- Adequacy.
- A reasonable degree of constancy and uniformity of illumination over the necessary area of work.
- The placing or shading of lamps so that light from them does not fall directly on the eyes of an operator when engaged on his work or when looking horizontally across the workroom.
- The placing of lights so as to avoid the casting of extraneous shadows on the work.

Natural light is to be preferred, on grounds of health as well as of economy, and roof lighting to lateral lighting. With a good system of roof lighting the illumination is very uniform.

The position of permanent working points should be so adjusted in relation to the windows and to internal obstructions in order to secure, so far as practicable, adequate daylight for each, and the effect of light-coloured walls and white ceilings on the general brightness of the room and in affording an effective background to dark objects should not be overlooked.

A shop where the ceiling is uniformly whitened and lighted by arc lamps shaded from the workers is illuminated by an agreeable diffuse light which casts no shadows. To produce the best effect the entire top surface can be covered with sheets of metal and enamelled white. Such a method of lighting may prove to be more costly in up-keep, but it has compensatory advantages in promoting the health of the workers, and thus may prove to be

economical in the long run. Lighting by fish-tail gas burners is very poor, but excellent lighting is obtained by the use of incandescent mantles and gas under pressure. The lamps in lofty shops can be placed high up so that they shed a diffuse light without directly throwing a glare into the workers' eyes. Abundant evidence has been obtained that when lighting conditions are improved there is a gain both in respect of the quantity and quality of the work. Failure to keep windows and skylights clean is a great source of economic loss. Windows should be hung on swivels so that they can be swung round and cleaned.

Eye-strain.

Eye-strain and headache are caused by unsuitable lighting and by the employment of workers on fine work without first testing their eyesight. The standard suggested as the minimum is $\frac{2}{3}$ in both eyes (Snellen's types) — $\frac{1}{2}$ in one eye may suffice in some cases—and the ability to read standard type 0.45 at 1 ft. distance. Any worker who complains of frequent headaches, pains in the eyes, or shows signs of conjunctivitis, should be tested again. The frequency with which conditions calling for treatment occur is shown by the experience of one factory where 8 per cent. of the workers had been obliged to obtain glasses since starting work; 12 per cent. found sight difficult at night, 7 per cent. complained of eye-strain, and 10 per cent. appeared to have latent eye-strain. Among women machining shells only 18.7 per cent. of eye defects was noted. In the fuse department, on the other hand, where fine processes demand close attention, there was 64 per cent.; 8 per cent. of the workers had been obliged to obtain glasses since starting work; 19 per cent. complained of eye-strain; 10 per cent. in addition appeared to have latent eye-strain as shown by headache, blepharitis, etc.

SICKNESS AND ACCIDENTS.

In investigating the question whether conditions in the factory are causing sickness among the workers, absence, broken time, irregular time-keeping, or diminished output of the individual worker must be recorded; and the sickness register, kept by a duly authorized officer, scrutinized weekly. If in any factory there be an undue proportion of sickness, it will usually be found that there is lessened vigour and activity among those not actually sick, for disabling conditions or influences which make some definitely ill injure all the workers in the factory. Fluctuations in sickness rates are mainly seasonal; the rate is always above the mean in January, February, March, and April, and occasionally in November also. July and August and December usually show least sickness; holidays may partly account for this. In some localities and kinds of work, however, hot weather causes an increase of sickness.

Medical Examination.

The foundation of any sound system of dealing with industrial disease lies in prevention and the recognition of the beginning of disease. The first step, therefore, is to provide for the medical examination of all workers on their admission to the factory, in order to ascertain that they are, initially, physically fit for employment. In some munition works there is in addition, in special departments, a periodical medical examination.

Having made sure that the individual worker begins well, the management must eliminate as far as possible all conditions which favour the occurrence of accidents by providing for the effective guarding of machinery, the use of safety appliances, the regulation of dangerous processes, careful cleaning of machinery, and adequate lighting. For the individual it must provide proper sanitary conditions and canteen facilities, and an adequate medical and nursing scheme. The appointment of trained nurses for both day and night shifts has proved of great value to employers and workers alike, particularly in factories where women are employed. The duties of a factory nurse include (a) supervision of the health of the workers, (b) superintendence of the rest room for those who are temporarily indisposed, (c) following up cases of sickness at home, (d) first aid treatment of injuries, and (e) in the absence of medical advice observing and controlling in its initial stages any threatened outbreak of the influenza type of sickness, which, if it extends, may temporarily paralyse output.

In times of peace a large number of accidents, of greater

or less severity, occurred in factories, particularly in metal, engineering, and shipbuilding works; many accidents, therefore, were to be expected in munition factories, where metal and engineering work and certain dangerous trades and manufactures are carried on, and where many of the workers are inexperienced.

For the avoidance of accidents and the prevention of serious consequences of slight injuries intelligent and vigilant supervision by the foreman is necessary, and a sufficient number of workers should be trained in first aid to ensure that there are one or two persons so trained in each shop. An aid post or local dressing station is established in each workplace and provided with sterilized dressings, triangular bandages, alcoholic iodine solution, and a bottle of eye-drops; it is placed under the charge of some person, trained in first-aid work, preferably the foreman or forewoman. There is also a central dressing station, providing a surgery, a rest room, a store room, and nurse's room. It has impervious washable walls and floor, hot and cold water laid on to a sink, and a foot-bath. Here the cases dressed at the aid post can be dressed again if necessary, and more serious injuries dealt with. It is provided with stretchers, splints, and bandages for major accidents, and a store of bandages and dressings for minor injuries, from which the aid posts are replenished, a simple sterilizer and necessary surgical implements, and simple lotions and drugs. Preferably it is put in charge of a trained nurse, who should have ambulance assistants selected from employees trained in first-aid work. Many large works now have a medical officer on the staff responsible for the supervision of the surgery and available for serious cases before removal to the hospital. A record of each case is kept, the nature of the injury, the way in which it was caused, and the progress of the case being recorded. The patient is supplied with a card giving instructions as to dates of attendance, and so on. The need for a medical organization of this kind is shown by statistics; in eleven works of moderate size, employing 35,000 workers, 38,000 surgical dressings were performed in the first ten months of 1915, the ratio varying from 19 per 1,000 employed per month to 221 per 1,000. In Woolwich Arsenal the organization, central and local, includes nine medical officers (two women), a matron, four nursing sisters, and a large staff of nursing orderlies and clerks. In 1914-15 there were 150,000 attendances for treatment or medical examination.

INJURIES OF THE EYE.

The importance of organizing suitable treatment of eye injuries is very great; apart from the risk of permanent injury, the loss of time through neglect of trivial accidents to the eye, due to delayed or unskilful treatment, is very serious. The Moorfields Eye Hospital in London recently reported that it was receiving about a hundred cases a week from munition and armament factories, involving the loss of three hundred days a week, or, say, forty men idle a week from this cause. At the Birmingham Eye Hospital about 15,000 cases of eye injuries are seen annually; the majority are slight, but even in these, when promptly treated, the loss of time to each man averages half a day, so that in this one district alone from five hundred to seven hundred days' work are lost annually from trivial accidents. At the Royal Eye Hospital, Manchester, it is estimated that small chippings of metal in the eye cause the injured person to be absent from work on an average for three days. By neglect to prevent sepsis a trivial injury may be converted into one which runs a prolonged course, and may lead to more or less impairment of sight, or even loss of the eye. The attentions of fellow-workmen at the time of the accident should be limited to the use of suitable eye-drops provided by the management. There is still a great prejudice among workers against the use of goggles, but in many classes of work it is essential to guard the eyes against flying particles of metal. The eye-guard should be strong and cheap, light and comfortable, allow free play of air, and not impede vision. Protection is required in front, below, and on either side, but the upper part may be left open for ventilation. Glass or other transparent medium, after a time, becomes pitted and obscured, and the guards, therefore, should be so made that the glass can be easily removed and replaced. Experience shows that there is no danger to the eye should the glass be broken by flying chips.

(To be continued.)

British Medical Journal.

SATURDAY, JULY 21st, 1917.

MESOPOTAMIA.

A FORTNIGHT ago it was pointed out here that a careful study of the report of the Parliamentary Mesopotamia Commission showed that one of its most important conclusions—that in which the opinion was expressed that the medical defects disclosed in Mesopotamia were not due to the shortage of river transport—was not justified by the facts set out elsewhere in the report, but was, in fact, in direct contradiction. The demonstration of this error justified the suspicion that the conclusions of the Commission in other respects should not be accepted without close examination. The two days' debate in the House of Commons last week brought out many other instances, and Mr. Balfour expressed a very widespread opinion when he said that the general character of the manner in which the Commission approached the question was not the proper method of dealing with great State affairs. To condemn anybody or punish anybody, or remove any one merely on the strength of the Commission's report would be, he said, to inflict a grave injustice upon individuals, and it was the business of Parliament not to be misled by the stream of public opinion, however natural, and "to be thrown over some cataract of public immorality." He exonerated the Commission from any desire to do anything but strict justice, but pointed out that its method of dealing with the great questions involved made strict and fair justice almost impossible. We believe that he expressed the considered opinion of the country in attributing the breakdown of the medical arrangements mainly to the general lack of adequate medical equipment, due to the deliberate policy of the Indian Government and the House of Commons of cutting down military expenditure. That there was a medical catastrophe after Ctesiphon no one can seek to deny, but the defeat at Ctesiphon was in itself a catastrophe, and it is undoubtedly true that when a defeated force has to retreat through a country overrun by marauders, the wounded must suffer if they are not to be left behind to have their throats cut. The main fault attributed to the responsible officers on the spot was in not foreseeing the possibility of defeat and retreat, and to apportion the blame among them is a task which Parliament cannot itself undertake, while the Government declares that it cannot treat the findings of the Commission as a judgement upon which punitive steps could properly be founded without further proceedings. In its search for a tribunal the Government first proposed to make use of an Act passed last year to meet a special case and to appoint under it a body consisting partly of legal members, but when the objections to this course were developed, it offered to pass a special Act appointing a special tribunal. After some days' consideration, however, both these proposals were abandoned, and the Government fell back upon the plan of leaving the Army Council to deal with military officers in the ordinary way.

The Parliamentary Commission has, in fact, itself been on trial, and its chairman in its defence has stated the procedure followed. Every witness was requested to put in writing the statement he wished to make, was then examined on it, the record of this examination was sent to him for correction, and the

corrected record alone used as evidence. The facts stated and recorded in the narrative of the campaign were contained in documentary evidence laid before the Commission. All documentary evidence was sworn to and all oral evidence was on oath. In a few cases in which statements were made by subsequent witnesses affecting previous witnesses and the fresh evidence was used, the witness so affected was recalled and re-examined. The contention founded on this is that the natural course would be for the Army Council to ask each officer concerned if he has anything to say or further facts to bring forward, and if he has, to appoint a military court of inquiry. The Government and the House of Commons have now decided that this course shall be followed, and we have no doubt that the officers concerned will welcome the decision. The services of Lord Hardinge as Permanent Under Secretary of the Foreign Office are to be retained, at the instance of the Foreign Minister, and apparently other civilians could be dealt with by the heads of the departments to which they belong. It must not be forgotten that the primary fault lies with the Finance Department of the Government of India, acting with the approval and, indeed, under the impulsion of the House of Commons.

The Chairman of the Parliamentary Commission has himself appealed to Parliament to "drop this useless and fantastic innovation of a special tribunal, and the waste of time which its discussion entails, and give its attention to those reforms in Indian administration the urgency of which is so clearly shown by our report." On this we would only say that this urgency, in respect of medical matters at least, was not shown for the first time in the report of the Commission. On the contrary, every one of its recommendations with regard to medical administration has been made time and again, but has been turned down on the ground of expense.

THE CENSUS OF 1911: OCCUPATION AND HOUSING.

II.

At the 1911 census information was sought by means of which classification, both by personal occupation and by industry, could be effected. It is impossible within our limits of space even to summarize the results, and we merely glance at a few points of interest. Taking the industrial classification (net total in industry or service), domestic indoor service still claims the largest total of employed persons, 1,302,438, of whom 1,260,673 are females. Agriculture is a good second with 1,229,555, and an easy first as an occupation for men with 1,134,714, followed by coal mining, which employs 971,236 persons, of whom 968,051 are men.

The figures for agriculture are very remarkable. For the first time since 1851 the number employed has increased, a diminution of 11.8 per cent. (using comparable figures) being converted into an increase of 5 per cent. Actually 69,475 more males were returned as employed in this industry than in 1901. The question whether this change is due merely to difference of classification or method is discussed, but no explanation along these lines is forthcoming. The returns of the Board of Agriculture and Fisheries of area under crops and head of live stock do not provide any definite confirmation of an increased agricultural development since 1901; the tentative suggestion is put forth that an extension of fruit farming and market gardening may have contributed in some counties to arrest the decline of the number of persons classified as farm workers.

With regard to women in industry, comparison is best made with the unmarried, as this group has been less affected by changes in the method of return. In both sexes the proportion occupied in the age group 10 to 15 has declined since 1901, but while the proportions of occupied males in age groups 15 to 20 and 20 to 25 have remained nearly steady, those of occupied unmarried women have considerably increased. In each successive decade up to 55 to 65 the increase in the proportion occupied was much greater for single women than for males.

From the tables showing the proportions occupied an estimate can be formed of the numbers of women available to recruit industries in such times as the present. The age group showing the highest proportion of occupied single women is 20 to 25, where it is 777 per 1,000; this compares with 974 per 1,000 males of the same age. In the words of the report, "The possibilities of recruitment of the ranks of labour from this source are, therefore, considerable, though not as great as is, perhaps, sometimes assumed. They may, no doubt, also be increased in times of stress by diversion of some of the existing labour from its normal employment, such as domestic service and the making of clothing."

In 1891 and 1901 the number of rooms occupied by a family had only to be recorded when the occupancy was of less than five rooms; in 1911 every occupier had to return the number of rooms in the occupation of his family, while, for the first time, a definition of the term "room" was attempted.

The commonest size of tenement was found to be that consisting of four rooms (nearly 25 per cent. of the whole); about 21 per cent. consisted of five rooms; tenements of three and of six rooms were about equally common, amounting in each case to about 14 per cent. of the total, so that over 73 per cent. of the total tenements were of from three to six rooms; 5.1 per cent. of the population were housed in tenements of ten or more rooms, 7.5 per cent. in tenements of not more than two rooms. Analysis of the population housed in tenements of less than ten rooms shows that a little more than 9.1 per cent. were housed under conditions allocating more than two persons to the room, a class designated in former census reports as "overcrowded."

It appears probable that the number of tenements of less than five rooms existing at the time of the last two censuses was much understated, seemingly on account of the form of question used, which led to the assumption that, when the number was unstated, the tenement really consisted of five or more rooms. This would explain the apparent increase of tenements of three rooms having more than two occupants to the room. Tenements of one and two rooms, which declined between 1891 and 1901, still further declined between 1901 and 1911. The tenement statistics for the county of London show considerable variations from those of the country as a whole, especially in the predominance of the smaller tenements. Of 1,000 tenements occupied by private families in London, 541 are of less than four rooms, 324 of from four to six rooms, and only 135 of more than six rooms; in England and Wales as a whole, the proportions are 255, 593 and 152 respectively.

The proportion of children under ten years of age to total population in each size of tenement is highest (27.4 per cent.) in tenements of two rooms, and gradually diminishes as the size of the tenement increases, being 6.4 per cent. in tenements of ten or more rooms. Tenements of less than five rooms comprised more than 70 per cent. of the total in twelve of the large towns (including London), the

highest percentages being 83.1 at South Shields and 82.9 at Gateshead. In twelve others the proportion was less than 25 per cent., the two lowest being Handsworth with 15.2 and Leicester with 17.5.

We next come to statistics of buildings. The number of inhabited buildings or "houses" was 7,141,781 compared with 6,260,852 in 1901; the average number of persons to an inhabited building was 5.05, against 5.20 in 1901. Among the large towns, the highest average was 8.23 at Devonport, the lowest, 3.97, at Halifax. Such comparisons are not, however, very illuminating, as size is not taken into account, a factor which also affects the value of contrasting tenement statistics.

DENTISTS AND MILITARY SERVICE.

THE Local Government Board has issued a memorandum announcing the arrangements agreed to for the time being by the Army Council with regard to dentists whose names appear in the current *Dentists' Register* and who are in actual practice. Men who were under 35 on January 1st last, and are fit for general service, unless exempted on local or personal grounds, will be available for military service. Men of 35 and over, as well as men of any military age who are not fit for general service, whose local claim for exemption is not upheld, may be granted exemption if they place themselves at the disposal of a Dental Service Committee, about to be set up, to utilize their services in some district where they are urgently needed. This Committee will contain representatives of the British Dental Association, a medical representative, and representatives of the Government departments mainly concerned. Its duty will be to ascertain in what areas there is urgent need for dentists, and to assist dentists who are exempted from military service for the purpose of practising in such areas in complying with that condition. The secretary's address is 19, Hanover Square, London, W.1. The Army Council reserves the right to take a registered dentist of any military age, and in any medical category, for duty with the army in his professional capacity if it wants him. The reason for all this is given in a footnote which states that the Central Tribunal "from evidence submitted to them are impressed with the danger of further reducing the number of registered dentists now in this country. Whether any particular dentist should be granted exemption must obviously depend to some extent upon the requirements of the place in which he practises, but they are inclined to think that unless it be shown that his services are not required he should be granted exemption." It will be observed that registered dentists of military age, but over 35, or unfit for general service, are to be given two alternatives—army conscription or occupational conscription—their professional services being made use of in either case. The Army Council, with the concurrence of the Local Government Board, intends, therefore, to apply to the registered dental profession a form of pressure which has not hitherto been applied to any other section of the community. There is plenty of evidence that in many districts there are not enough dentists for the needs of the civil population, and the army also, we believe, is under-staffed with dentists; but the proposed arrangement is open to criticism on various grounds. In the first place, no reference is made to medical men who are at the same time on the *Dentists' Register*. Presumably it is not meant that they should be affected, but that the Central Medical War Committee should deal with them as though they were in medical practice. This is an unsatisfactory position, and we should like to know that the Central Medical War Committee has formed a definite policy with regard to men with medical and dental qualifications who

are engaged in the practice of dentistry. Questions next arise as to the functions and powers of the new Dental Service Committee, which is to place out dentists in districts where they are urgently needed. The composition of this body does not suggest that it will possess the requisite knowledge of the dental needs of the community, or the machinery for obtaining such information. Again, what will be its criterion of dental needs? Already a considerable number of unregistered dentists have been exempted by local tribunals in the alleged interests of the teeth of the industrial population. Will the Dental Service Committee ignore the presence of unqualified practitioners in estimating the dental needs of any given district, or will it confine its attention to those areas in which there is a shortage of both registered and unregistered dentists? Such questions occur at once, and cannot be lightly put aside. The committee did not create the anomaly of the ubiquitous unqualified dentist, but we fail to see how it can do much good if it evades it. By the law of the land dentistry is a branch of medicine. The General Medical Council keeps the *Dentists' Register*, supervises dental education, and takes disciplinary action against registered dentists. The dental business of the Council is transacted, in the first instance, by a Dental Committee of the Council. Just as there is no separate General Dental Council, so it would seem undesirable to set up a distinct Dental Service Committee working altogether apart from the Central Medical War Committee, and unaided by its organization. The fusion of these two bodies would not, it is true, solve the problem of the unregistered dentist in relation to the needs of the industrial population; but a Dental Service Committee as a branch of the Central Medical War Committee would be in a far better position to acquire knowledge and take action than as an isolated body. The Army Council and those advising it do not seem to have taken a wide view of the matter.

FARM COLONIES FOR TUBERCULOUS SOLDIERS.

DURING the past year the National Association for the Prevention of Consumption has urged the formation of farm or garden colonies where discharged tuberculous soldiers, while regaining their health, may be trained in open-air occupations. At the annual meeting of the association on July 16th Professor Sims Woodhead sketched his own idea of a model farm colony. It should consist of a large enough tract of land to allow variety in the forms of cultivation introduced. The aim was not only to provide the patient with suitable and congenial work, but also to give him an occupation which should serve him as a means of livelihood, and a part of the farm colony, therefore, should be laid out on a generous allotment system. The colony should serve as an educational centre and show how much could be done to improve the conditions of farm workers and the hygiene of farm buildings. To that end every farm colony should be a microcosm in which the maintenance of health and the prevention of infection should be absolutely secured. He thought also that accommodation should be provided for advanced cases. As far as possible, the patients should do the whole work of the colony themselves, and even the overseers should be tuberculous patients who were coming to the end of their term. The patient should help to contribute to the cost by his own labour. The State must provide the land, and it might also contribute towards preparation of the land and erection of the general buildings. But the special buildings, particularly the hospital buildings, should be jointly provided by local taxation, Treasury loan, and voluntary subscription. As the patient got stronger a certain portion of his earnings should be set aside as a bonus for him when he made a new start in life. In the subsequent discussion Sir R. W. Philip suggested that there was some risk of opening the door of the farm colony too wide. If the colony was to be a dumping ground for all grades of tuberculosis, its purpose

would be defeated. There must be a clear separation between early and presumably curable cases and dying cases; for the latter, of course, humane provision must be made, but not that of a farm colony. The class of cases to be taken were those which lasted a much longer time than the sanatorium could afford to keep them. Sir William Osler said that the essence of success in the treatment of the consumptive soldier was that he must remain a soldier—that is, he must be under control. Discipline was a very necessary factor in the life of a farm colony. Sir A. Griffith-Boscawen, M.P., Parliamentary Secretary to the Ministry of Pensions, said that his department had been faced with the difficulty that medical boards had generally assumed that when a man was discharged for tuberculosis the condition was not attributable to military service, and the result was that until lately the man had been turned adrift without pension or other provision. In France in such cases the benefit of the doubt was given to the man. The conditions of the service might at least have brought out the disease earlier than it would otherwise have manifested itself. The policy now was to assume in all cases that the disease was the result of military service unless the contrary was clearly proved.

SELECT FLAPDOODLE.

RUMOUR, according to Skeat, is from a root *ru*, meaning to make a humming noise, as insects that gather together and fly away apparently haphazard, but keeping in a bunch. So with certain sorts of mankind, who love to fuss and hum and buzz in bunches. Instances are afforded by some kinds of members of Parliament and journalists. The war has produced several examples. For some months the buzzing was all about slackers who would not go and fight, and young men out of khaki went so much in dread of reproaches in public places that a buzzing arose that they should be badged. Now the buzzers are off on another breeze, and have their stings out for the recruiting department and its medical examining boards because they are endeavouring to do the irksome duty imposed on them by the Legislature, with the approval, if not at the instance, of these very same members of Parliament and journalists. No feebler, more illogical, case than was made during the recent debate in the House of Commons on the administration of the Review of Exceptions Act can ever have been put to a village debating society; one member after another got up and talked balderdash, yet Mr. Macpherson, for the War Office, threw over the recruiting department and medical examining boards, and put their critics on to a "select" committee. It may be that the methods of the recruiting department under the Review of Exceptions Act, the instructions issued by it to the medical examining boards, and the constitution and method of procedure of these boards call for inquiry. A large department—which in the old conscript countries has been built up through very many years of work and experience—has had to be improvised here, and it is more than likely that mistakes in principle and detail have been made, but to refer the matter to such a select committee as this was not the right way to put things straight. The "select" have been roving at large seeking out scandals, and have succeeded in unearthing a certain small number of mistakes made by medical boards—possibly five in a thousand of the men sent to the boards by the recruiting officers to be examined. We are in the midst, perhaps in the crisis, of the greatest of wars, and the proceedings of the "select" are sheer waste. They have caused the waste of acres of paper and of uncounted hours of work of honest printers; yet there is a great shortage of paper and of printers to do work that will help to get on with the war. Again, the armies in France, in Macedonia, and in Mesopotamia are in daily need of drafts to meet the daily wastage among the men who are doing their duty in the fighting forces. Every man whose name appears in the long casualty lists must

be replaced. But the efforts of the "select" have the effect of checking the replacement. The energies of the chiefs of the recruiting department are being used up to satisfy the curiosity of the "select," and the men—so to call them—who wish to shirk are clogging snooks at the local recruiting officers and invoking the names of the "select." There was another concession made as a result of this same debate which is not working well. The Government promised that all men who had served abroad and had been discharged from the army, but were now coming compulsorily under the Review of Exceptions Act, would be finally discharged if they made a claim. This may be only justice to many such men, but in this wholesale form the concession works practically as an injustice to others. Early in the war the Army Council, we believe, adhered to the old-standing principle that if a man could not be made fit to rejoin his unit in six months he should be discharged, and probably many men discharged in these early days are now fit to serve, if not in the fighting line, then in various capacities behind the front or in this country. As it is, men who were wounded later are not now being discharged automatically under the six months rule, but, after a proper interval of treatment, are examined with a view of ascertaining whether they can be of use to the army in any capacity; they may well feel that there is a discrimination against them. Nobody wants to bear hardly on men who have done their bit, but there should be even justice for all.

THE TREATMENT OF TETANUS.

A THIRD edition of the Memorandum on Tetanus, by the War Office Committee for the study of that disease, has been issued. The full text of the second edition of the memorandum was published in the *JOURNAL* of November 11th, 1916, p. 647. The new edition follows the general line of the second, but has undergone revision. In discussing the therapeutic or curative treatment, the Committee now states still more emphatically than before its opinion that "in acute general tetanus the best method of treatment lies in the earliest possible administration of large doses of antitoxic serum by the intrathecal route, repeated on two, three, or four days in succession, and combined, if thought desirable, with intramuscular injections," the latter being the appropriate form of treatment of chronic forms of tetanus, particularly localized tetanus limited to one limb. The Committee further states that experience has shown that in the treatment of acute general tetanus the best results are obtained from very large doses of serum, and that "the more acute the case the larger should be the dose of serum employed. The object is to saturate the body with antitoxin as quickly as possible, and to maintain the saturation. For this purpose from 50,000 to 100,000 units may be given during the first few days of treatment." Tetanus antitoxin is issued to military hospitals in two strengths, and for acute general tetanus the high potency serum, put up in phials of 8,000 units, should be used. In an introduction to this third edition the question whether the memorandum is to be looked upon as an army order or as a number of suggestions which may or may not be carried out, according to the inclination or judgement of the officers in charge of hospitals, is dealt with. It is stated that in so far as the memorandum concerns the prophylactic or preventive treatment it is to be regarded as an army order, but in so far as it concerns the therapeutic or curative treatment, as containing suggestions; for it has never been the policy of the army medical authorities to interfere with the treatment of the sick soldier by his medical adviser.

THE SOLDIER'S HEART.

CARDIOLOGISTS have approached the subject of the soldier's heart from many points of view, and the conclusions arrived at and the recommendations for treatment have been almost as numerous. In his recent Chadwick lecture,

published in the *Middlesex Hospital Journal* (May, 1917), Dr. J. S. Goodall has brought them under review and has roughly classed them as optimistic and pessimistic. The former all put faith in some form of treatment, but the latter form the majority. By analysis of a large number of cases he is led to the opinion that over-irritability, sometimes of the nervous mechanism and sometimes of the muscular, is the main feature of the condition generally described as soldier's heart. This excess of irritability may be due to emotion, overwork, excessive use of alcohol or tobacco, or to insufficient rest. Believing that a very high proportion of cases of Graves's disease are produced by shock, nerve strain or violent emotion, he regards many forms of cardiac irritability in young subjects as being due to hyperthyroidism. The relation of suprarenal activity to tachycardia is also discussed, but no positive conclusions can be drawn from the evidence available. The heart muscle may acquire over-irritability and the result produced upon the cardiac action will depend upon the integrity or otherwise of the paths of cardiac impulse, which in itself may originate elsewhere than in the sino-auricular node. From the clinical point of view the irritable heart, due to overwork and insufficient rest, is generally found to lie more or less horizontally and is described as "soft and squashy." A similar condition is noticeable among old men or among workers who suffer from chronic toxæmia of any kind and after infective fevers. As regards diagnosis it is maintained that the best test is the reaction to graduated exertion. It will be remembered that in his report on the results of observations at the Hampstead Hospital and elsewhere, Dr. Thomas Lewis expressed the same views and advised that method of diagnosis and prognosis in preference to any of the time-honoured physical signs. The practical outcome of the study points to the need for greater care in graduating the training of recruits. Over-strain, especially in the early stages of training, must be avoided and adequate rest must be provided after special exertion, more particularly in cases where the man has been recently the subject of any infective illness.

WAR EMERGENCY FUND OF THE ROYAL MEDICAL BENEVOLENT FUND.

ABOUT a year ago an appeal was made on behalf of the War Emergency Fund of the Royal Medical Benevolent Fund. This fund is intended to help medical men who, when called up to serve with the military forces, had to leave on very short notice, without time to make adequate provision for the continuance and maintenance of their practices during their absence. Such men have had to face a severe fall in income, while many expenses, such as rent, insurance, taxes, family maintenance, and education, could not be reduced. In a year or two after their return they will, it is hoped, recover their position, but in the interval they may stand in much need of help, and it is to meet such needs that the War Emergency Fund has been established by the Royal Medical Benevolent Fund. The list of those who have responded to the appeal made last year is published at p. 25 of our advertisement columns and contains many liberal donations. We notice, for instance, sums of £280 contributed by the West African Medical Staff in Nigeria through Dr. W. I. Taylor, of Lagos; of £150 (first instalment) by the Otago Division of the British Medical Association, and of over £95 collected from his friends by Dr. G. Maxwell Simpson. Such examples may well be followed by other medical organizations and members and Divisions of the British Medical Association, for the need is great, and the sum already received (£4,000) in response to the appeal made last year falls very short of the £25,000 which the committee managing the fund considers to be necessary. In this appeal the Royal Medical Benevolent Fund is supported by the Presidents of the Royal Colleges of Physicians and Surgeons in England, by the Directors-General of the Medical Departments of the

Royal Navy and of the Army, by the Regius Professors of Medicine in the Universities of Oxford and Cambridge, and by Sir John Tweedy, a past President of the Royal Medical Benevolent Fund.

THE WAR COLLECTION AT THE ROYAL COLLEGE OF SURGEONS.

MODESTY is an uncommon virtue and the more prized on that account, but it may be carried to excess, and this has happened with regard to the war collection at the Royal College of Surgeons of England. Though small, it is very interesting, but it is very badly displayed; it is crowded together in a small room not too well lighted. Not only are the stands too close together, but they have too many shelves, and there are too many specimens on each shelf; to inspect them properly the visitor ought to be something of a gymnast or contortionist, able to study a specimen by looking with his head through his knees. The error is the more striking because there is close by a well-lighted room, almost empty, which would afford ample space for the display of the specimens at a convenient level for the eye. We understand that the collection will be enlarged and rearranged for the opening of the winter session in October, but we would suggest that something might be done at once, for the collection now is not only interesting but instructive, and its instruction is wanted now by the surgeons who have to treat the wounded. There are already some bone specimens which throw a vivid light on what goes on in an infected bone wound; there is, for instance, one of an excised upper part of the humerus, but there are many others. We hope that Professor Shattock, the pathological curator, and the other authorities of the College, will look at the matter from this point of view—namely, the importance of the collection to surgeons at the present moment; it would be better to risk loss by a stray bomb than loss of knowledge now urgently needed.

MINISTERIAL CHANGES.

It cannot be said that the ministerial changes announced on July 18th have aroused any enthusiasm or materially added to the strength of the Government. The resignation of Mr. Austen Chamberlain is a real loss, the extent of which has only been accentuated by the masterly speech in which he announced his retirement. He has been a sincere friend of India, and has shown noteworthy appreciation of the importance of the application of scientific knowledge and method to the welfare and health of the teeming millions of that great country. Mr. Winston Churchill has another opportunity to prove his capacity for high office, and everyone will hope that he may show the judgement and constancy needed for that to which he is now appointed. He has a difficult task in succeeding Dr. Addison, who has been a member of the Ministry of Munitions since its formation, and as Minister has shown, to quote the words of the *Times*, "capacity, foresight, and no little courage in grappling with difficult industrial conditions." As Minister in Charge of Reconstruction (without portfolio) he will have no easy task, for which, however, his long apprenticeship to social work particularly qualifies him. Reconstruction will include problems of demobilization, some of which are already arising; they will affect the medical profession not only directly, inasmuch as the number of medical men to be demobilized eventually is large in proportion to the total number of the profession, but also indirectly, through the effect of the demobilization of our large combatant forces, and the return of the men to civil life. Reconstruction is not altogether a matter for a far-off time of peace. In order that the best possible may be obtained from the nation, reconstruction must be continually going on, even in time of war, and it is possible that the new Minister of Reconstruction may find matters in connexion with the relation of the Army Medical Department to the civil community and the civil medical profession which merit his attention.

THE QUEEN'S VISIT TO FRANCE.

DURING the visit of the King and Queen to the armies in France Her Majesty spent most of her time in seeing the medical arrangements behind the lines. A comprehensive tour had been arranged by Sir Arthur Sloggett, Director-General A.M.S., and, acting on his advice, Her Majesty found it possible to visit the more representative hospitals at all the bases. Particular attention was paid by the Queen to the arrangements for the nursing staffs, including their mess huts and sleeping quarters, and the homes for sick sisters and for those who are convalescent. The Queen also inspected the convoys, which at certain bases are in charge of women drivers and are responsible for the carriage of the wounded between the trains and the local hospitals.

PROFESSOR HARVEY LITTLEJOHN, Dean of the Faculty of Medicine, University of Edinburgh, informs us that he knows of several senior students who are anxious to do hospital work or to help in practices during the summer vacation; he will be glad to answer communications. From inquiries occasionally received it appears that there are senior students at other schools who are anxious to act as residents in hospitals, temporarily, but we are not aware how far the hospitals are prepared to entertain such proposals.

In a leading article published by the *Times* in one of its issues last week there is a passage which shows that the respective duties of the Army Medical Service in India and the Indian Medical Service were not understood, or had been forgotten, and as the error has not, so far as we have observed, been corrected, we think it necessary to call attention to the facts (see p. 83). In dealing with the responsibilities of individuals, the *Times* article spoke of excuses made for the Indian Medical Service. We are not aware that it has been considered necessary to make excuses for any officers of the Indian Medical Service. Sir William Babbie, who was mentioned by name in the *Times*, is a distinguished officer of the Army Medical Service, and to the same service belong Surgeon-Generals MacNeece and Hathaway.

Medical Notes in Parliament.

The Mesopotamia Report.

SHARP CRITICISMS IN THE COMMONS.

THE debate in the Commons on the Mesopotamia report, on July 12th and 13th, was somewhat sensational in character on account of its reaction against the findings of the Commission and also because of the unexpected resignation of the Secretary of State for India, Mr. Chamberlain, who nevertheless made a vigorous and spirited defence of his conduct. At the onset the Attorney-General, in stating the legal position which the Government had been obliged to consider, reminded members that the Commission had no judicial function and that the evidence had no legal value. Therefore, if any action was to be taken against the person censured a fresh inquiry must be instituted. Mr. Chamberlain in his speech showed that the report was misleading in certain essential particulars. Mr. Balfour in defending Lord Hardinge censured the censors. Mr. Asquith surprised the House by alleging that he had nothing to do with the critical decision for the fateful advance towards Bagdad, and Mr. Lloyd George took up earnestly a suggestion by the ex-Premier that in the existing conditions of the war there should be no further proceedings inasmuch as they would not conduce to the prosecution of the war, which was the supreme need. Such were the principal features of the Commons' discussion.

The points brought out can easily be indicated. Sir F. E. Smith, in his trenchant speech at the opening, quoted the terms of reference to the Commission in proof that it was appointed to report upon the responsibility of departments of Government concerned in this campaign,

and not to pronounce a final judgement on any individuals. The witnesses were expressly indemnified both in regard to their evidence and the production of documents. No charges were made, and none of the persons censured had been recalled for the purpose of presenting any defence to the allegations which were evolved in the course of the inquiry. After each witness had given his evidence he departed, and Sir F. E. Smith told the House emphatically that it would be a travesty of justice if disciplinary action were to be taken upon findings reached by the Commission in these circumstances. No court, he said, would convict the meanest criminal under such conditions. In illustration of what happened, he said that a favourite method of eliciting a conclusion was for a member of the Commission to say to a witness in the box, "Now, tell me, who do you think is responsible on the whole for this?" The Attorney-General was unable to quote the evidence, because, of course, if any quotation had been made in the House, all the evidence would have had to be presented, and it is reckoned against the public interest that the notes of evidence should be issued at present. He next discussed the question what course could be taken. He showed that a court-martial at the present stage could not be contemplated because of all the lengthy preliminaries that would have to be gone through with witnesses scattered over great distances and with the probability that the matter would not be concluded within the period fixed by the Statutes of Limitations for such cases. The Government favoured the use, for setting up a fresh court of inquiry, of an Act passed last year, to meet a case in which both military officers and civilians were involved. This provided that three military officers and two judges or ex-judges should form the tribunal. The Attorney-General admitted that the procedure was not exactly suited to the present matter. In fact, as Mr. Montagu afterwards pointed out, civilians would come before the court only as witnesses, whereas military persons involved would be the subject of the court of inquiry. Indeed, it appeared as if unless the military subordinate chose to defend himself by making a charge against the officer, the officer's conduct would never come before the inquiry. The Attorney-General did not contest this definition, but maintained in effect that the tribunal would serve the purpose. He intimated that the Government was willing, if the House preferred it should do so, to set up a special tribunal by means of a bill. In either case the Government would pay all expenses for the defence by counsel of persons involved. But the one thing to which the Government was absolutely committed was that under no circumstances would it sanction punitive action as the result of the report of the Commission.

It became quite evident as the debate proceeded that the House regarded the first proposal of the Government for an inquiry as unsatisfactory. But it was not until Mr. Chamberlain rose that the situation really became dramatic. Lord Hugh Cecil, who was a member of the Commission, said earlier in the debate that there was no idea, he believed, of punishment in the criminal sense of the word on the part of the Commission. It had been concerned with administrative efficiency and responsibility, and he declared his amazement at finding it was supposed to have recommended that the War Committee of the Cabinet should be impeached. Mr. Chamberlain startled the House by announcing that he had tendered his resignation of his position as Secretary for India because he felt that he could not appropriately hold it while his conduct was under censure and subject to inquiry. He mentioned that this decision was final, and its acceptance was only delayed by the absence of the King from the country. Mr. Chamberlain's speech was one of the ablest he has ever delivered, and, though he apologized for frequent reference to notes, saying that he made these references because of the need for accuracy, he did not thereby weaken his hold at the House in the slightest degree. In particular he was concerned to correct a misleading impression given by the Commission in its suggestion that the War Committee took the course it did. As to the advance towards Baghdad "for political considerations" because there was "great need of a striking success in the East," Mr. Chamberlain, in tones of warm indignation, said that by the mutilation of telegrams the Commission had led people to think that the Government, to restore their shattered fortunes, had deliberately sent men on a hazardous gamble. To correct this matter, Mr. Chamberlain paraphrased the telegram as it ran in the original, filling in the gaps left in the report of the Commission. The blank which he supplied made the passage read as follows:

It would seem that Persia is drifting into war on the side of our enemies. The Arabs are wavering and will probably join the

Turks unless we can offer them a great inducement. We are therefore in need of a striking success in the East, both to prevent Persia being carried away and to secure the support of the Arabs.

Mr. Chamberlain was interrupted by Sir Archibald Williamson, another member of the Commission, who said that it was impossible for the Commission to publish this matter fully, but Mr. Chamberlain retorted that no opportunity for misunderstanding ought to have been allowed. He went on to tell the full story of the circumstances in which the Baghdad advance was sanctioned. He brought out the fact that the matter was referred to the combined general staffs, and that the War Committee acted on the unanimous advice of their military experts both at home and in India. He also stated, on information from Sir John Nixon himself, that the Turkish reinforcements which turned the scale actually arrived only on the day of the battle of Ctesiphon.

Mr. Chamberlain afterwards dealt with the hospital arrangements. He said he did not offer one word of excuse or palliate the horrible breakdown which had occurred. But he pointed out that he was for fifteen or sixteen months without information upon which he could act, and he claimed that when he could he did so with all possible energy. As to the private telegram to the Viceroy regarding the threatened concentration of 60,000 Turks which the Commission blamed him for not forwarding to Sir John Nixon, Mr. Chamberlain said that it never was supposed to be the duty of the India Office to convey military intelligence to India. That was done by the War Office, and Mr. Chamberlain put it that this telegram was really a personal matter.

Mr. Balfour was even stronger in his criticism of the Commission. After deploring that Mr. Chamberlain had resigned, he said that in his opinion the Commission was quite as much on its trial as any of the gentlemen they had arraigned. He referred to the way in which they had blamed Lord Hardinge for not transmitting to Sir John Nixon the telegram about the threatened concentration of Turks, and said that so far from either Mr. Chamberlain or Lord Hardinge being criminals in that matter, if any persons were criminals it was the Commission, who must be so labelled for presenting the matter as it had. Mr. Balfour warmly defended Lord Hardinge, saying that the latter had twice tendered his resignation of the permanent Under Secretaryship of Foreign Affairs, but that he (Mr. Balfour) had refused to accept it. In regard to the transport deficiencies and the medical breakdown Mr. Balfour presented his own view without hesitation. He reminded the House of the way in which India had been bled white in providing men and supplies, including medical supplies, for theatres of war outside India. He recalled that Lord Hardinge had in pre-war years deliberately exceeded by two millions a year the expenditure reckoned by Lord Nicholson's Commission to be needed for military purposes, those purposes being defined as security from external land attack and internal revolution. He pointed out the exiguous position in which the Indian Government had been placed, and said in short that India, like Great Britain, was unprepared for this war, and that what had happened was very like what had happened at home when we found ourselves short of munitions. He further insisted that such a catastrophe as this always occurred when an army advanced far into a savage country where the wounded could not be left, if as in this case, a reverse occurred. He held that the Government had had to depend upon Sir John Nixon's assurance and the military expert opinion that the advance could be made; if it could have been done there would have been no breakdown, inasmuch as instead of having 3,500 wounded there would not have been more than 500.

At the sitting on Friday, July 13th, Sir Archibald Williamson, a member of the Commission, defended the report, but asked the House to distinguish between the conclusions of the report and the conclusions of the newspapers, which, he said, were entirely different. He defied any man with balanced judgement to read the report carefully and to read what was said by the newspapers and to find the same result from the two readings. Captain Aubrey Herbert said that he had returned from Mesopotamia burning for the punishment of certain men, but even more anxious for the salvation of the troops there. What was the debate doing, he asked, to help on the war? It seemed to be a national habit whenever we got into difficulties to appoint a commission to increase them. Loss of time meant loss of lives. There had been a sub-war all through the war of one department against another. No man had a greater admiration for the R.A.M.C. officers in the field, which he had witnessed on many fronts; their sacrifices were without limit, but the corps had suffered from the aggressive departmental spirit. There

had been a spirit of jealousy; in Mesopotamia it was generally considered that the Indian Medical Service was more broad-minded and tolerant. There had been a vast improvement in the R.A.M.C., and the far-reaching reforms introduced had made the system in France almost as perfect as it could be. He deplored, however, the lack of frankness in dealing with deficiencies in Mesopotamia and the Dardanelles which affected the lives of men, and he said that where that lack of frankness occurred, it seemed to him as bad as treason in the field. At the same time, and especially in the case of Sir John Nixon, whose qualities he eulogized, Captain Herbert deplored newspaper trials.

The speeches of Mr. Asquith and the Prime Minister came near the end of the debate. The ex-Premier, who scarcely ever refers to the newspapers, quoted from a "paper" which, he said, was called *The Morning Post*, wherein he had been accused of being the "villain" of this piece and Mr. Chamberlain his victim. Mr. Asquith mentioned that during the period when the decision for the advance towards Baghdad was taken he was for ten days on the sick list and forbidden by his superior authority (his doctor) to attend to any public affairs. He defended the decision, however, and claimed to be an accessory after the fact. In face of the unanimous expert opinion in favour of this undertaking the War Cabinet would have been told that they were a set of "timorous, pigeon-livered politicians, cowardly, fearful to take risks," if they had refused to accept that advice. Coming to the present situation, Mr. Asquith spoke of the difficulty of setting up a new tribunal, and, as already has been stated, raised the question whether in the present warstrain it was desirable to spend time and labour in going over this matter. He asked whether it might not be better in the existing circumstances to attend to "the capital matters"—a phrase which he drew from a quotation from Burke sent him by a correspondent a few days before. That passage concluded, "Applaud us when we run, console us when we fall, cheer us when we recover, but let us pass on; for God's sake let us pass on."

The Prime Minister, somewhat to the surprise of the House, returned to the first of the two alternative proposals made by the Attorney-General on the previous day and declared his preference for it, believing that it would be workable and adequate. He stated, however, that the matter seemed to him to be one for the House, and he went on to take up the suggestion of Mr. Asquith that it might be better not to set up another tribunal. He made perfectly plain his wish that, if offences had been committed and they were serious, they should have severe punishment, but he asked the House to reflect that twenty millions of men were at that hour interlocked in deadly conflict for the future of the world. He told the House that for two or three days the Army Council, the chiefs of the army, the War Cabinet, the House of Commons, and the House of Lords had been discussing the methods of dealing with the findings of this Commission, which had nothing to do with the practical prosecution of the war. He mentioned, too, that he had been called from a meeting of the heads of the Admiralty and of shipowners on the important question of protection against submarines, in order to give his mind to this subject. He appealed to the House not to lose its sense of perspective, but to rise above these things and to say to the Government: "Get on with the war."

The only subsequent speaker was Commander Wedgwood, author of the minority report, and the debate then lapsed.

Sir Henry Craik on the Contradictions of the Report.

In the course of the debate on July 12th on the Mesopotamia Report Sir Henry Craik said he had a large number of constituents who were in the medical profession, especially in the Indian Medical Service and in the R.A.M.C. He had studied what the report said with regard to the profession, and found its conclusions vague, indiscriminate, and even contradictory. In illustration, he quoted paragraph 111, which said that passages in the evidence of Lord Hardinge, Surgeon-General Hathaway, "and other responsible witnesses" might lead to the inference that the medical breakdown in Mesopotamia was due to the shortage of ordinary river transport, for which, of course, the medical authorities were not responsible. The report said that if this were true it would follow that the medical authorities must be relieved of blame, yet it went on to say it could not agree with such a contention. In other paragraphs of the report the Commissioners pointed out also that if the medical authorities were not responsible for the ordinary river transport they must be relieved of all blame, and yet

elsewhere said that, in their opinion, the known shortage of ordinary river transport, if anything, aggravated rather than palliated the omissions of the medical authorities. Sir Henry asked how these contradictions were to be reconciled. It seemed to him that the Commission desired to find in some way or other a scapegoat and had found him anywhere except in the right direction. The long history of the medical services in India had been a fight against the most miserable cheese-paring by the financial authorities in India. He put far more trust in the conclusion of the Vincent-Bingley Commission than the more sweeping conclusions of the Parliamentary Commission. The Vincent-Bingley Commission urged over and over again that the evil had come from the way in which the medical service had been starved. Referring to the position of Sir William Babbie, Sir Henry Craik said that because in the nine months he was in India he did not reconstruct the whole medical service, breaking through the bonds and shackles that had been imposed by years of service, he was blamed. That single reflection by the Commission, constituted as this was, on a man with the record of Sir William Babbie, was an absolute mistake. In concluding his short speech Sir Henry protested that the medical men should not suffer in this way whilst the Financial Secretary to the Indian Government was given, as he understood, a higher and more important post.

DEBATE IN THE HOUSE OF LORDS.

The debate in the Lords, which also took place on July 12th and 13th, did not add much information. Lord Lansdowne, speaking as a former Viceroy, ascribed much that had happened of late in India to the changes made in 1905 and 1908 in the military system. He referred especially to cutting out of a supply member from the Council, when the "one man" arrangement was made. The supply member was the official to whom the India Government would have looked when the questions as to transport and supplies arose in regard to the advance to Baghdad. Lord Loreburn construed the report as not reflecting on the honour of any one, but as simply saying that there was want of foresight and that there were errors of judgement. He asked whether any one doubted that this was the absolute truth. He was against the appointment of a new court of inquiry. He saw no ground for imputing to any of the officers such conduct as would justify a court-martial, and as for the civil servants, if the Government thought that any should not remain in the service, the Government had the remedy in its own hands. Lord Curzon, in replying at the close of the discussion, assured the House that the Government had no desire to minimize the gravity of the report nor to condone the errors it revealed. Neither did it desire to condemn any one unheard. The public was anxious that the guilty should not escape, and he earnestly hoped that they would not. But it seemed to him that the demand for victims had almost degenerated into the witch hunting of barbaric times. Lord Curzon added that the things which were the subject of condemnation in the report might have been avoided if they had not been working with a radically unsound and vicious system of administration in India.

THE GOVERNMENT DECISION.

Mr. Bonar Law stated on July 18th that the Government, after further consideration of the action which ought to be taken in regard to individuals whose conduct was criticized in the report, had decided not to proceed further by way of a tribunal set up either under the Act of last year or by a special Act. In coming to this decision it had been influenced by the undesirability of diverting the efforts and energies of the legislature and executive at this critical stage from the prosecution of the war. In regard to soldiers, the Government had decided that they should be dealt with in the ordinary way by the Army Council, whose decision as to the action to be taken by it would be announced as soon as possible. He concluded by stating that the Government had decided not to accept the resignation of Lord Hardinge (Permanent Under Secretary, Foreign Office). A debate raised by Mr. Dillon on the adjournment turned entirely on the position of Lord Hardinge. On a division Mr. Dillon's motion was rejected by 171 to 81.

Army Medical Officers' Pay.—Colonel Gretton asked Mr. Forster whether he was aware of the disparity between the pay of medical officers belonging to the Territorial Force and those who had recently joined the Army Medical Corps, and if he was aware that majors serving

as medical officers in the Territorial Force received the same pay as a recently joined lieutenant of the Army Medical Corps. Mr. Forster replied that the Territorial Force officer was paid at the same rate as the regular R.A.M.C. officer of the same rank and services, except that only embodied service counted for increase of pay in the same rank. The comparison which Colonel Gretton wished to make was probably that between the pay of the Territorial Force officer and of the temporary officer engaged on special contract terms during the war. When allowances and terminable gratuities were taken into account, the major of the Territorial Force received considerably more than the special contract officer.

The Pay of Admiralty Local Surgeons.—Mr. French asked whether local surgeons and agents of the Admiralty were receiving only 2s. 6d. per patient for professional attendance and supplying medicine to the Coastguards and men of the Royal Navy and 1s. per mile one way for locomotion expenses. Dr. Macnamara replied that the rates were, with a few exceptions in which the higher rates were warranted, 2s. 6d. per visit to or consultation with each patient (and not as the question might perhaps imply, 2s. 6d. a case). Only one application for increased remuneration had been received during the year, although there were some 550 surgeons and agents. In the circumstances a case for a general increase had not been established. In answer to another question, Dr. Macnamara gave particulars to show that between 84 and 85 per cent. of the accounts received in April and May were paid within two months of receipt, 70 per cent. being paid within six weeks. Moreover, arrangements were in force by which payments on account amounting to any claim exceeding £10 were made immediately on receipt.

The War Pensions Bill.—The War Pensions Bill was read a second time on July 17th after being amended at the instance of the Minister of Pensions. The bill winds up the Statutory Committee, transfers the powers of that committee to the Ministry of Pensions, authorizes the Ministry to set up a Special Grants Committee, and makes certain provisions with regard to the Royal Patriotic Fund. The Ministry will administer the warrant of March 6th directly, determining whether a person, including widow, dependant, or parent, is entitled to a pension under the terms of the warrant. The Special Grants Committee will have power to supplement pensions deemed to be insufficient in any particular case, and will, in particular, have power to increase the allowance to a parent of 15s. a week or more under the warrant to a maximum of 30s. The money in the hands of the Statutory Committee—about £12,000 or £13,000—received from voluntary subscribers, will be turned over to the Royal Patriotic Fund for use in very hard cases that cannot be met either by the Ministry or its Special Grants Committee.

Army Medical Examination Committee.

At the meeting on July 12th of the House of Commons Committee on Army Medical Examinations, Mr. Mooney presiding, evidence was given by Sir Ryland Adkins, M.P., a member of the Northamptonshire Appeal Tribunal, and formerly chairman of the General Recruiting Committee of Northamptonshire. He was of opinion that the doctors forming the boards were overworked and had to do things too quickly. The medical boards should, in his opinion, have power to call before them any doctor who had given a certificate in respect of a man called up; and the medical man so summoned should have a reasonable allowance for appearing before them. He further suggested that there should be a medical tribunal to which a man could appeal if his category was raised by his commanding officer and medical officer.

Mr. A. Richardson, M.P., Chairman of the Law Society Appeal Tribunal, gave some particulars of cases sent up from this tribunal to the Special Medical Board. Of the 120 cases submitted for re-examination 38 were of men passed for general service by a local medical board. Of these 32 were on re-examination rejected or placed in lower categories. He suggested that where a man had to make an irrevocable decision, such as the sale of a business, the tribunal should have the power to say that he should be finally examined before he took that step. He further suggested that a tribunal to consist of civilian and military members should be set up to inquire into cases on the part of members of medical boards, and with power to suspend any member who was guilty of gross neglect.

The committee adjourned until July 16th.

Evidence was given on July 16th by Colonel Peterkin, Director of Medical Service in the London District. He said that following upon a letter received on September 16th, 1916 (in terms such as had been quoted by previous witnesses), he sent out a circular to the boards in his district, calling their attention to the large number of medical rejections. He mentioned that some of the boards had over 40 per cent. of rejections, and said that they must be brought down to the very lowest proportion.

The Chairman produced returns showing the comparative

number of rejections in the various districts before and after the circular was issued. This was as under:

		Before.	Fortnight After.
		Per cent.	Per cent.
Whitehall	(1)	20.4	4.6
	(2)	28.4	9.9
	(3)	17.3	6.8
White City	(1)	31.4	12.8
	(2)	32.7	15.9
Camberwell	(1)	26.2	23.6
	(2)	21.9	18.2
Stratford	(1)	9.4	4.9
	(2)	17.1	6.5
Shoreditch	21.5	7.0
Chelsea	43.6	3.1
Holborn	28.1	7.7
Battersea	28.8	9.5
St. Pancras	38.4	8.9
Woolwich	28.8	9.8

The witness was subjected to a lengthy examination by Mr. Pringle as to the lessening of the rejections. He accepted the principle that men earning a livelihood in civil life could do some work in the army, but said that the instructions to the medical board had to be read in the light of common sense. Any man with serious heart disease would not be passed into the army. He had no doubt that errors had been made and always would be. It was quite possible that numbers of men who had passed into the army by medical boards had within a few weeks found themselves in hospital; that had happened even in peace times occasionally. Questioned on the terms in the circular he issued, Colonel Peterkin held his suggestion to be chiefly for the retention of men in C 3.

The decisions of the Mill Hill and the Hounslow Medical Boards were criticized at the sitting on July 17th by Mr. E. S. W. Hart, secretary to the Middlesex Appeal Tribunal. Speaking generally of the work of the medical boards which had been reviewed by the Middlesex Appeal Tribunal, he said that examinations began to be most unsatisfactory about the middle of 1916. There had lately been an improvement.

Mr. Donald Maclean, M.P., Chairman of the London Appeal Tribunal, quoted a statement by Mr. Barnes, the Pensions Minister, as showing that there were many thousands of men still in the army who ought never to have been there. This was inferred from the pension cases which came before Mr. Barnes's department. On the point of need for care in passing men, Mr. Maclean said it must be borne in mind that the country was getting "very near the bone" in respect of recruitable men who were fit in any degree of army medical fitness. The public should not lose sight of the fact that the branch of the army concerned with medical examination and classification was more or less a scratch organization, and every allowance should be made for mistakes in the very remarkable work that had to be done; there was still an amount of hasty and ill-considered classification of men for the army, and there was also a good deal of malingering. He considered that appeal tribunals did admirable work in adjusting the mistakes made by medical boards throughout the country; that medical men as well as politicians were liable to make mistakes. Mr. Maclean was not altogether in favour of the appointment of men "at the top of the tree" to compose the special medical boards; there should be one hundred special medical boards all over the country. Doctors could, he believed, be easily found from the large number of fair-minded men who would command the confidence of all sections of the country. They need not be specialists of world-wide eminence, but men of common sense and sympathy, and of sufficiently high medical attainments to say whether from a common-sense point of view a man should render military service or remain in civil life. The witness was asked by the Chairman of what value this arrangement would be if the category of a man after enlistment was liable to be changed by a commanding officer and medical man. Mr. Maclean replied that he was not dealing with that point, but speaking only of his experience of tribunals. He fully agreed that in a number of cases a man's condition might improve after enlistment.

THE British Museum (Natural History), South Kensington, S.W.7, has issued two wall placards, the one on "the fly danger," and the other "the mosquito danger." Both have drawings of the insect, and, in the case of the mosquito, of the larva and pupa as head pieces. Below are printed very clear instructions as to their breeding places, their destruction, and preparations for protecting rooms and individuals. We may quote the sunlight trap for flies: "Close all windows and doors, and darken all windows except one, freely dusting the one light window with Keating's powder." In trying to expel mosquitos, it is advised that a well-lighted window or door should be left open for the insects to escape, and shut half an hour after fumigation with Keating's power or cresol. We hope that both placards will have a wide circulation both in this country and overseas. There is sometimes difficulty in obtaining the publications of the Natural History Museum, but we assume that in this case the placards, the price of which is 4d. each, will be sent on an application, accompanied by a sufficient margin for postage.

THE WAR.

MEDICINE IN THE SPRING OFFENSIVE.

CHANGES.

It is impossible to be at a casualty clearing station at the front without realizing that one is close to a war, and it is impossible to be anywhere near the front without realizing that war is progressive. The front is a world not only of constant movement but of constant change. Divisions come and divisions go, and camps erected to-day are moved to-morrow.

Even when trench warfare had so long persisted that there seemed to be no other form of warfare local changes were constant, and during the past twelve months, when large sections of the British line have advanced considerably, the changes have not only been constant but general. The armies have grown persistently, centres of activity have moved, and arrangements of medical units have been affected correspondingly. Indeed, the extent to which they have been affected has exceeded that of other units. For front line medical units have a way of becoming rapidly very elaborate institutions. Many of the advanced dressing stations, for instance, are very solidly built structures. So, too, are often the rest camps and other annexes of field ambulances, while, as is well known, casualty clearing stations rapidly develop into real hospitals. Nevertheless, at almost a moment's notice the word comes, and off they go; however elaborate and beautiful, their existence is ephemeral. Possibly their habitations are taken over by a unit of the same type; possibly by another branch of the army altogether; possibly they are broken up; possibly our allies get the benefit of them.

At the bases the position is rather different. Here it is possible to have no very acute evidence for weeks together that a war is in progress. Though there are always patients suffering from wounds, the sense of progress and movement is lacking and the general feeling may be one of stagnation. But even here there is no real stagnation. Hospitals are enlarged and hospitals are improved; changes of staff are frequent; new treatments are tried or established, and a hospital which has previously been accustomed to receive one class of case finds that it is called upon to do a new kind of work. This has always been the case, and of late the great increase in the size of the British Forces in France has been made apparent by the springing up of new convalescent camps, and the favourable progress of the war evidenced by the gradual moving up of camps of the same order which are known to have been previously working elsewhere.

But beyond this there is evidence of a change not perhaps perceptible to those who stand too close. There is a tendency to make the front line medical units play a larger and larger part in the general medical arrangements. The proportion of operations undertaken at the front grows steadily larger as the result of a definite policy on the part of the medical authorities, which must undoubtedly be greatly to the advantage of the wounded man; its net effect on the base hospitals, however, must be sooner or later to alter the character of their work. They will be merely resting houses between the hospitals at the front and those at home.

COMPARISON WITH THE SOMME.

The principles that underlie the arrangements for the collection, evacuation, and treatment of casualties during an offensive are the same on all occasions, but their application differs with the precise circumstances. Thus, in the Somme offensive last year the advances were never deep on any one day or during any week, and positions were constantly being lost and won. Consequently there were frequently occasions on which considerable numbers of wounded men could not be brought in forthwith; and as the weather was rainy, though not cold, their condition was often very bad when they were picked up.

Little by little the extent of the advance deepened, and the fighting troops got further and further away from the advanced dressing stations, main dressing stations, and casualty clearing stations that had been organized. The fighting, moreover, took place in a hilly country of woods and loamy fields, and as miles of it had been converted by heavy rain and shell fire into thick mud, the movement of

casualties became increasingly difficult as time went on. The roads, initially very few, were badly cut up and crowded with traffic, so that the progress of ambulances was slow and difficult. For long it was impossible to make new roads or run up tramway lines on which stretcher lorries could be carried.

THE ANCRE.

In the Ancre offensive the advance was rapid and prolonged, so rapid that the fighting troops soon got many miles away from the main dressing stations and the lines of casualty clearing stations behind them. For several of these miles the roads were so cut up that motor ambulances could not traverse them, and there was one particular place in front of the main dressing stations which for some time could not be traversed even by horse ambulances. For a stretch of country immediately behind the fighting troops the roads were good, and from this point to the roads nearer the old British line the patients were conveyed partly by hand carriage, partly by wheeled stretchers, partly by such horse ambulances as had managed to get through. But arrived at the broken ground they all had to be off-loaded and carried for a mile or more by hand and then reloaded on ambulances on the other side. Consequently the time taken in reaching the casualty clearing stations was longer.

VIMY.

In the Vimy fighting the position was again different. The advance was rapid and completely successful from the beginning. Consequently the wounded were not left out owing to positions being taken and retaken. In addition, the depth of advance did not extend for more than a few miles. It is true that these few miles were, as a rule, a sea of mud, and made bearer work exceedingly difficult and profoundly exhausting; but as soon as the old British line was reached there were tram-lines on which stretchers could be carried and decent roads along which ambulances could move to the main dressing stations. But although these roads were initially good and the tram lines were very soon pushed forward over the mile or two of mud, the weather conditions were deplorable. When it was not raining it was snowing, and the snow was often heavy. Movement therefore from the advanced dressing stations to the main dressing stations was often difficult. Furthermore, some of the main dressing stations were necessarily at a rather long distance from the casualty clearing stations serving them; this was particularly true of the upper two-thirds of the line of offensive. The condition was quite inevitable, because the area is one in which military and civil conditions made it impossible to place casualty clearing stations as close to the trenches as elsewhere. The roads, moreover, are hilly and difficult to keep in good repair, and the heavy snow and rain cut them up with great rapidity. Hence the time taken in reaching the casualty clearing stations from the main dressing stations was often long.

MESSINES.

In the Messines offensive the picture was again quite different. The action was, from a medical point of view, more in the nature of a huge trench raid than an offensive. It was short and sharp. The casualties did not exceed expectations and the military programme was successful in every detail. This area has been longer held than any other, and the medical arrangements had been made long in advance, and the military operations having been carried out precisely according to programme, the medical arrangements were likewise successful. In all cases the success of the medical arrangements largely depends on the success with which such matters as the total number of casualties and the points at which they will chiefly occur have been calculated, and that depends on the degree to which the offensive is a military success. The calculation involves, of course, a careful forecast by the medical authorities of the military situation on the day of battle, and this is only possible when the official and personal relations of the D.M.S. of an army with the commander of that army and the rest of the staff, as also those of the principal medical officers on the staffs of the commanders of corps and divisions, are of such a nature as to allow of the closest co-operation.

As already suggested, all the anticipations in regard to the Messines offensive were, in the event, justified to the

full, the result being that the advanced dressing stations and the collecting aid posts for slightly wounded men were found to have been placed exactly where they were required. Furthermore, they had been linked together by tramway lines carrying lorries for the conveyance of wounded men, and all roads along which ambulances were to travel had been carefully determined in advance. Equally careful arrangements had been made close to the field of action for separating the severely wounded from the slightly wounded or walking cases, and for winnowing out from the walking cases the men who were merely exhausted or overstrained. Many men, of course, found their way to the rear on foot, and along the roads which it was known they would probably travel coffee stalls had been placed; when they arrived at certain points they were able to continue their journey by means of a series of char-à-banc cars, which plied continuously between the picking-up point and the formations in the rear for slightly wounded or exhausted men. The net result was that the medical units doing operative work were never overcrowded, no patients reaching them except those who really required attention. They were visited during the course of the offensive both by the Commander-in-Chief and the Director-General, and after the affair was over we hear that the commander of the army concerned issued a general order thanking the medical units for their work, and deputed the Director of Medical Service of the army concerned to visit all the field ambulances which had taken part in the operations and thank them in his name.

MEDICAL CASUALTIES.

It is clear, therefore, that on this, as on so many previous occasions, the medical service thoroughly justified its reputation. The casualty lists that have since appeared indicate that the R.A.M.C. by no means escaped scot-free, but any one who is acquainted with the condition of modern warfare must know that this is practically inevitable. Casualties do and must continue to occur, even though the medical officers are not expected, and are in fact forbidden, to expose themselves more than is absolutely necessary for the performance of their duties. Their right place is now considered to be with the head quarters of the battalions to which they are attached, and it is no longer their duty to hunt under fire for places which may serve as regimental aid posts when battalions are taking part in an advance. Such precautions may no doubt lessen, but cannot prevent, casualties among battalion medical officers in the conditions of modern warfare, and they leave unaffected the dangers to which field ambulance medical officers in charge of stretcher parties are inevitably exposed.

CLEANSING OF WOUNDS.

The view held by the Director-General of Medical Services in France and his staff is that the most important point in the treatment of casualties is the mechanical cleansing of their wounds and the excision of all badly torn tissues, and that so far as possible such treatment should be administered before a patient is evacuated to a base. Casualty clearing stations as a whole have been putting this principle into effect for more than a year so far as ordinary trench warfare is concerned, but it has not been easy for them to do so when large offensives are in progress, or the fighting is for some reason unusually heavy. To meet the difficulty of large offensives special arrangements have been made this year, the principle of operating teams by which the casualty clearing station staffs are reinforced on the occasion of offensives being progressively increased; the net result is that among patients who required operations at all, the proportion of operations undertaken close to the real front was very much larger during the Messines fight than on any previous occasion. The advantages of this increased proportion seem to be amply demonstrated by the reports as to the condition in which the wounded reached base hospitals.

In the fortnight following the attack the mortality seems to have been only 1 per cent. of all cases; there were hardly any cases of secondary haemorrhage, and extremely few amputations. There was also a notable absence of cases of massive gas gangrene; in fact, there was very little gas gangrene at all, and the majority of cases that did occur were among patients who had to be sent an unusually long distance.

SPLINTING AND THE SUPPLY OF SPLINTS.

On all occasions it is the duty of a unit receiving a patient on a stretcher to hand back a stretcher forthwith to representatives of the unit from which the patient arrives, and during the Messines offensive the same principle was applied to Thomas's splints. This is now regarded as the splint for routine use right away down from regimental aid posts.

The Thomas thigh splint is applied at regimental aid posts over the clothes, without removal of the patient's boot. The result of the principle of handing out a splint for every splint received on a patient was that the regimental aid posts never ran short, and no patients were ever sent to the rear until their limbs had been rendered thoroughly steady. The adoption of this plan is considered to have helped materially in the prevention of shock, and to have contributed not a little to the excellent medical results noted in this offensive. It is the practice now to apply splints not only to cases of fractured bone or injured joints, but also to cases which present nothing more than an extensive wound in the soft part.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Accidentally Killed.

The battleship *Vanguard*, 19,250 tons, was blown up by an internal explosion while at anchor on the night of July 9th. She carried a ship's complement of 62 officers, and over 700 lower ratings. Of these, 24 officers and 71 men were on leave ashore at the time; of the rest only two men survived. Among the 38 officers lost were three medical officers, Fleet Surgeon E. Cox, R.N., Staff Surgeon W. G. Barras, R.N.V.R., and Surgeon E. Rayner, R.N.

FLEET SURGEON E. COX, R.N.

Fleet Surgeon Edmund Cox, R.N., was the youngest son of the late Surgeon-General Charles Lindsay Cox, I.M.S., was educated at Cambridge and at the London Hospital, and took the M.R.C.S. and L.R.C.P.Lond. in 1899, also graduating as B.A.Cantab. in 1895, as M.B. and B.C. in 1900. After acting as clinical assistant in the medical out-patient department of the London Hospital, he entered the navy as surgeon, and attained the rank of fleet surgeon on February 11th, 1917.

STAFF SURGEON W. G. BARRAS, R.N.V.R.

Staff Surgeon William George Barras, R.N.V.R., was the only surviving son of Dr. John Barras, who four years ago resigned the position of medical officer of Govan parish, which he had held for fifty years. He was educated at Glasgow and Durham universities, graduating M.B. and C.M.Glas. in 1889, and M.D. in 1892, and also taking the L.S.Sc. at Durham in 1890, and the D.P.H. in 1903. After filling the posts of assistant medical officer of health and bacteriologist to the burgh of Govan, he went into practice at Govan, Glasgow, where he was physician to the Elder Cottage Hospital. He took a commission as surgeon in the R.N.V.R., Clyde Division, on November 10th, 1904, and was promoted to staff surgeon on November 10th, 1912.

SURGEON E. RAYNER, R.N.

Surgeon Edward Rayner, R.N., was educated at Cambridge, where he graduated M.B. and B.C. in 1912. He took a temporary commission as surgeon in the navy on August 6th, 1914. He was the son of the late Edward Rayner, of Beechlands, Wadhurst.

ARMY.

Died of Wounds.

CAPTAIN A. G. PETER, M.C., R.A.M.C.

Captain Alastair Gordon Peter, M.C., R.A.M.C., died of wounds on July 5th. He was the youngest son of the late Mr. John Peter, factor to Lord Lovat, and was educated at King's College, London, and at Aberdeen University, where he graduated as M.A. in 1898, and M.B. and Ch.B. in 1903. He took the M.R.C.S. and L.R.C.P.Lond. in 1907, and the D.P.H. at Cambridge in 1910. After serving as assistant medical superintendent of the St. Pancras Infirmary at Highgate, as assistant medical officer of the Brook and Grove hospitals of the Metropolitan Asylums Board, and as bacteriologist and deputy medical officer

of health to the borough of Croydon, he went into practice at Inverness, till he took a temporary commission in the R.A.M.C.

CAPTAIN H. E. ROSE, R.A.M.C.

Captain Harold Emerson Rose, R.A.M.C., died of wounds on July 7th. He was the son of Mr. J. A. Rose, of 36, Apsley Road, Bristol, and was educated at Cambridge, where he graduated B.A., and at Edinburgh, and took the Scottish triple qualification in 1913. He joined the Special Reserve of the R.A.M.C. as a lieutenant on September 2nd, 1914, and was promoted to captain after a year's service. He was attached to the Coldstream Guards when he met his death.

LIEUTENANT B. COHEN, R.A.M.C.

Lieutenant Bertram Cohen, R.A.M.C., was reported as having died of wounds in the casualty list published on July 13th. He was educated at St. George's Hospital, and took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1908, and graduated M.B., B.S. Lond. in 1912. After filling the posts of house-surgeon, house-physician, and resident obstetric assistant at St. George's Hospital; of resident medical officer of King George's Hospital for Officers; and of house-physician of the General Lying-in Hospital, Lambeth, he went into practice at Sidmouth, Devonshire, where he was honorary physician to the Victoria Cottage Hospital. On March 16th, 1914, he took a commission as surgeon in the Royal Naval Volunteer Reserve, and served for some time in the Royal Naval Hospital, Plymouth, but had recently taken a temporary commission in the R.A.M.C.

Died on Service.

LIEUTENANT A. ATKINSON, R.A.M.C.

Lieutenant Ambrose Atkinson, R.A.M.C., died suddenly at Felixstowe on July 7th, aged 57. He was educated at Leeds Medical School, and took the diplomas of M.R.C.S. in 1884, and the L.R.C.P. Edin. in 1892, afterwards acting as house-surgeon of the Leeds General Infirmary. He resided at Harringay, North London, till he recently took a temporary commission in the R.A.M.C., and was in medical charge of the 3rd Battalion Suffolk Regiment at Felixstowe.

Wounded.

Lieut.-Colonel W. H. R. McCarter, R.A.M.C. (temporary).
Captain W. A. Sneath, M.C., R.A.M.C. (temporary).
Lieutenant H. R. Grellet, R.A.M.C. (temporary).
Lieutenant J. A. McIlroy, R.A.M.C. (temporary).

Wounded and Prisoner.

Captain H. Stokes, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Belemore, Raymond A., Captain Connaught Rangers, only son of the late Brigade-Surgeon-Lieut.-Colonel A. J. Belemore, R.A.M.C., of Brighton, killed recently. He got a commission as lieutenant on August 7th, 1914, and had served in Mesopotamia.

Cook, Leonard Nield, Second Lieutenant Royal Lancaster Regiment, youngest son of the late Dr. J. Nield Cook, late Health Officer of Calcutta, killed July 7th, aged 20. He was educated at Bedford Grammar School and at Rugby, and gained a scholarship at Queen's College, Oxford, in October, 1915. He got his commission in December, 1915, went to the front in July, 1916, and gained the Military Cross last October.

Lloyd, John Wathen Eaton, younger son of Dr. Eaton Lloyd, Second Lieutenant Royal Flying Corps, killed June 24th, aged 22. He was educated at Epsom College, and articled to the Shotton Engineering Company, before he enlisted at the beginning of the war.

Rice, Bernard Neville, Captain East Yorkshire Regiment, elder son of Dr. Bernard Rice, of Westrock, Leamington Spa, died on July 10th, aged 22, in the Warneford Hospital, Leamington, of wounds received in France in June, 1916. He had won a classical scholarship at Balliol College, and was about to proceed to Oxford when the war began. He got his first commission on August 29th, 1914.

Stokes, Guy Lennard, Second Lieutenant Royal Field Artillery, second son of Dr. Lennard Stokes, of Blackheath, killed July 5th. He was educated at the Blackheath Proprietary School, and at the Central Technical College, Tunbridge, and was a well known Rugby football player for Blackheath and Kent.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

NOTES.

FOREIGN HONOURS.

A SUPPLEMENT to the *London Gazette*, dated July 14th, contains a further list of decorations and medals awarded by the President of the French Republic for distinguished services rendered during the course of the campaign; the list includes the following medical officers:

Légion d'Honneur.—Croix d'Officier: Lieut.-Colonel W. R. Blackwell, R.A.M.C. Croix de Chevalier: Major E. T. Potts, D.S.O., M.D., R.A.M.C.; Captain (acting Lieut.-Colonel) R. Magill, M.B., R.A.M.C. (S.R.); Captains W. H. P. Hey, M.B., F.R.C.S., R.A.M.C., and F. M. Hughes, R.A.M.C., temporary Captain G. Rankine, M.C., R.A.M.C.

Croix de Guerre.—Major W. H. K. Anderson, C.A.M.C.; Captain J. A. C. Scott, M.C., M.B., R.A.M.C.; temporary Captains T. Meagher, M.C., M.B., R.A.M.C., and C. S. E. Wright, R.A.M.C.

The Croix de Guerre has also been awarded to two non-commissioned officers and five privates of the R.A.M.C.; and two non-commissioned officers and four privates of the R.A.M.C., together with one non-commissioned officer of the C.A.M.C. and one private of the A.A.M.C., received the Médaille Militaire.

England and Wales.

TECHNICAL TRAINING OF DISABLED SAILORS AND SOLDIERS.

At a meeting of the London County Council, on July 17th, a scheme formulated by the Education Committee in conference with certain technical institutions for providing technical training for disabled sailors and soldiers was considered. It provides that all the disabled men shall be interviewed first by a rota of expert advisers from the institutions concerned. The trade panels (which have been or are being appointed by the London War Pensions Committee) will supply the rota with details of the outlets available, and particulars of special training for each type of outlet. The disabled man will then be directed to an institution, where he will be interviewed by the trade panel, and if it be decided that the training asked for is applicable to his case, he will be placed in turn for the starting of the next group in such training or for the next vacancy in an existing group. The committee will watch over the work and progress of the candidate, and at the end of his training will put him in communication with a firm willing to find specific vacancies for men so trained. The scheme came into operation as from July 1st. The London War Pensions Committee is to pay for teachers' salaries or part salaries in respect of this particular instruction.

THE PROPOSED MINISTRY OF HEALTH.

At the annual provincial meeting of the Society of Medical Officers of Health, held at Birmingham on June 30th, a paper was read by Dr. T. W. N. Barlow on "The status of the medical officer of health in relation to the proposed Ministry of Health." He deprecated the system under which seven or eight Government departments dealt with health matters, with the consequent overstaffing and overlapping. There should be centralization locally as well as at the centre. The existing health committees should be the nucleus of the new local bodies, and should have as an adviser the medical officer of health, who already had experience in the organization of tuberculosis work, school medical work, maternity centres, child welfare centres, and routine public health work. The President (Dr. John Robertson) said that the records of results attained in this country justified the claims of the medical officer of health to be the head of the new department, though he feared there was a lack of appreciation of what had been done, directly and indirectly, by medical officers of health. Lieut.-Colonel Herbert Jones urged the importance of medical officers of health having had experience in general practice. Professor Bostock Hill maintained that public health was developing on the lines of medicine rather than on those of pure science, and that the coming together of the general practitioner and the medical officer of health would be to their mutual advantage. Dr. Buchanan considered that the main conception of the Ministry of Public Health should be the care of the individual, and that the advisers of the Ministry should be trained in medicine, and possessed of organizing ability and imagination. Dr. Barwise, Dr. Halliwell, and Dr. Suell also took part in the discussion.

LONDON WATER.

Dr. A. C. Houston, Director of Water Examination, Metropolitan Water Board, in his eleventh annual report, which is much shorter than previous reports, records the results of the chemical and bacteriological examination of the London waters for the twelve months ended March 31st, 1917. During the year, 13,109 routine samples of water were examined, apart from a very large number collected for special purposes. In the twelfth research report,¹ Dr. Houston dealt in detail with the successful results of the chlorination of raw river water as an alternative to storage, and showed that a better water could be provided at much less cost, with consequent saving of coal. The dose of chlorine used varied from 1 in 1 to 1 in 4, but usually was 1 in 2 million parts of water. From June 1st, 1916, to March 31st, 1917, 17,180 million gallons were treated during 252 days (West Middlesex supply) and 224 days (rest of Staines supply) out of a total of 304 days. The net saving was £8,177. The bacteriological results of treatment from June to September, 1916, were very successful, although the water was not always completely sterilized. From October, 1916, to the end of March, 1917, that is, during the flood months of the year, the Hampton results are summarized as follows: 56.1 per cent. of the 100 c.cm. cultures for *B. coli* yielded negative results. This percentage was increased to 77.1 when the samples were kept before examination for an extra twenty-four hours in a bottle so as to simulate more closely the conditions in the West Middlesex reservoirs where the storage may exceed one to two weeks; the Staines stored water standard is 20 per cent. negative. As regards the 10 c.cm. cultures for *B. coli*, 85.4 per cent. gave negative results; the Staines stored water standard is 60 per cent. negative. Hence the treated river water was purer, as judged by the *B. coli* test, than if it had undergone prolonged storage in the Staines reservoirs. The treatment was also uninterruptedly successful in regard to absence of taste. The New River conditions are widely different. The storage is inadequate, and the rate of filtration is about double that practised at the other works of the Metropolitan Water Board. Owing to the New River containing a large proportion of well water the filtered results are on the average good, and, in the best months of the year, beyond reproach. When, however, floods occur in the Lee Valley, the results invariably deteriorate. There seems to be no remedy for this except by providing adequate storage and increasing the filtration area, but the cost would be enormous, as the daily output from the New River works is over thirty million gallons. If, however (says Dr. Houston), the judicious use of sterilizing agents could smooth over, or perhaps wipe out, the effects of flood, a case might be made out for at least deferring the construction of these expensive works. Towards the end of last year an attempt was made, with the co-operation of the engineering department, to achieve this object. The treatment lasted from December 24th, 1916, until January 12th, 1917, when it was stopped because the water had acquired an unpleasant taste. The treatment coincided with a period of intense cold, and, relative to that temperature, experience showed that the dose used was too large to prevent the water from acquiring a disagreeable taste. Despite the complete stoppage of the treatment the taste in the filtered water persisted for some time; this no doubt was due to the ability of the filter sand to "absorb" and "hold in store" taste-imparting materials derived from the previous treatment. This is one of the objections to chlorination before filtration. The bacteriological results during the treatment were very satisfactory. The treatment was tried again later, where much smaller doses were used with complete absence of taste. Experiments with liquid chlorine have been also started with gratifying results. Dr. Houston is convinced that by the exercise of the utmost vigilance and skill a chlorinated but tasteless water which is, relatively speaking, satisfactory bacteriologically can be produced even during floods. The margin between successful sterilization and avoidance of taste is not a wide one, particularly in cold weather and with a short contact.

The concluding part of the report is devoted to practical considerations on algal and other growths in water.

¹ BRITISH MEDICAL JOURNAL, December 9th, 1916, p. 816.

Ireland.

MR. DUKE stated last week that the Midwives (Ireland) Bill had been drafted, and that if he were assured that it would be non-contentious he would consult the Leader of the House as to its introduction.

COUNTY TIPPERARY (S.R.) MEDICAL COMMITTEE.

A complaint was forwarded by the Irish Insurance Commission to the Tipperary (S.R.) Medical Committee in connexion with a medical certificate issued in that area for sickness benefits by a doctor who had made no previous medical examination of the insured person. The doctor against whom the complaint was made having admitted the offence, the committee directed the secretary to inform the Commissioners that the case submitted for its observations showed a grave dereliction of duty on the part of a medical man involving a monetary loss to the aggrieved society, which in its opinion should be borne by the person responsible for that loss. Should the Commission, in the interest of efficient working of the Act, consider it necessary to administer a further correction, it was asked, considering that this was the first case in the area, that it might not be of as severe a nature as the Commission was entitled to enforce, and as the committee would feel compelled to suggest in case of a repetition of such an offence. The doctor referred to had never, to the committee's knowledge, attended meetings of the medical profession in connexion with the Insurance Act, and was therefore not perhaps fully aware of the obligations undertaken, yet he should have avoided committing an error which is deeply regretted by the committee.

DUBLIN UNIVERSITY AND THE WAR.

At a meeting in support of the Dublin University Voluntary Auxiliary Hospital, Miss Rachel Mahaffy, the commandant, submitted a report stating that 77 patients had been received during 1916. A motion by Sir Robert Woods, declaring the hospital worthy of the support of members of the university, was adopted. Professor Dixon, in seconding it, said that about 900 past and present members of the university were in the medical service of the Royal Navy, the R.A.M.C., and the I.M.S. Of 199 Irish and British men who had taken medical degrees in Dublin University, 196 had volunteered for one or the other of the three services, and the number would have been greater but for the fact that 175 medical students had volunteered for active service without waiting to qualify. Of the medical women graduates, seven were employed in the R.A.M.C., and several were taking temporary work to set free medical men for active service abroad. Of the members of Dublin University serving with medical units 135 had been mentioned in dispatches, 47 had been awarded the Military Cross, two had received a bar to that Cross, 31 had received the honour of D.S.O., 11 of C.M.G., 10 of the C.B., one of K.C.B., and one of C.I.E. In addition five had received foreign decorations.

Scotland.

PAISLEY BABY WEEK.

In common with many other towns, Paisley has had a "baby week"; in other words, there was a child welfare exhibition, designed to teach the gospel of health so far as infants were concerned; there were lectures and demonstrations given by members of the medical profession and health visitors, and representatives of the civic authorities made speeches exhorting the people to greater care of child life and commending the various measures which were being taken by the medical officer of health (Dr. G. Clark Trotter) and his assistants. The exhibition was open from July 9th to 14th. The Paisley infantile mortality-rate reached its lowest (92.15 per 1,000 births) in 1912; in 1913 it was 118.00, in 1914 it was 133.00, and for the past two years 106.00 per 1,000.

Sydney.

THE PROFESSION AND THE WAR.

At the annual meeting of the New South Wales Branch of the British Medical Association a resolution, recommending mobilization of the Australian medical profession, moved on behalf of the council by Dr. R. H. Todd and seconded by Dr. R. Gordon Craig, was carried unanimously.¹

It was also resolved that in grateful recognition of the loyal and devoted services rendered at this supremely critical period to King and empire by members of the Association, the names of all members who have already enlisted, or who, before the termination of the war, shall have enlisted for active service in the naval or military forces of the empire, shall be enrolled by the council in a suitable book to be preserved in the library of the Association.

HOSPITAL MAINTENANCE.

During last year a conference, comprising delegates from all the municipal councils in the State, was called by the Local Government Association to discuss the question of hospital maintenance. The committee of this association has prepared a report for submission to the councils, and an official summary of this report sets forth the following recommendations:

1. The existing system is not a complete and satisfactory fulfilment of the duty of the community to care for the sick.
2. We do not think any system can be devised, based on voluntary charity, which will keep pace with the growing needs of the hospitals.
3. We do not favour the complete nationalization of the hospitals.
4. We think it most important that the local government system should be applied to hospitals for the purpose of centring in the hospital local interest and local charity.
5. We believe that the problem will best be met by the grouping of the State into hospital districts, each consisting of a number of municipalities and shires surrounding the hospital centre.
6. We recommend the maintenance of hospitals by (a) patients' fees, (b) donations and bequests, (c) a levy upon the contributing councils, (d) a Government subsidy at the rate of £ for £ on the money raised from rates and £ for £ on the money chargeable against patients.
7. We recommend the constitution of hospital boards on a proper elective system, with one or more Government nominees and two or three co-opted members.
8. We believe that a uniform charge should be made in respect of each patient, such charge not to be enforced against poor patients who are unable to pay.
9. We believe that sectional hospitals which are offering benefits to the general public should receive a recompense from the public funds.
10. All matters of internal administration should be left to the hospital boards to decide.

This report and recommendations contain much of interest and importance to the medical profession, and no doubt the matter will be the subject of criticism and report by the council of the New South Wales Branch of the British Medical Association.

VENEREAL DISEASE.

The problem of venereal disease has occupied a large share of public attention during the past few months. An important conference was convened by the Public Morals Association last year. The following resolutions were carried:

- That in view of the revelations contained in the recent reports of the Federal Commission and the State Select Committee on Venereal Diseases, as to the serious consequences of these diseases on the birth-rate and on the rate of mortality among infants, and taking into consideration the historical evidence of the increase in incidence and severity of venereal disease during and after war, and with the object (1) of fostering infant life, more especially in view of the serious effect upon the marriage and birth rate likely to be occasioned by the unprecedented loss of life at this time; (2) of preventing the spread of these diseases to innocent victims, this conference respectfully urges the Government to introduce legislation requiring that the ceremony of marriage shall be conditional upon the production of a certificate of freedom from venereal disease.
- That all public general hospitals supported by State funds should be compelled to make provision for the treatment of patients suffering from venereal diseases, and that a suitable booklet should be given to each patient being attended either at a hospital or by a private medical practitioner.

That a council for combating venereal disease should be called into existence, to be recognized by the Government as an authoritative body, for the purpose of spreading knowledge in regard to the question of venereal disease in its varied aspects.

That this conference endorses the recommendation of the Royal Commission on Venereal Diseases that instruction in these subjects should be provided in evening continuation schools and in factories and workshops. For this purpose the aid of properly constituted voluntary associations should be enlisted, and the guidance of medical practitioners should be secured.

That this conference urges upon the Government the printing and circulation to every householder throughout the State of suitable literature dealing with the question of venereal disease; also the enactment of more stringent legislation providing for the suppression of advertisements, and of the circulation of all printed matter, dealing with sex complaints and their treatment.

That this conference urges upon the authorities the necessity for the better enforcement of the law to suppress houses of ill fame.

That this conference affirms its conviction that notification will not prove effective in staying the ravages of venereal disease, but, if enacted, is more likely to cause the victims to avoid treatment or to seek the advice of quacks.

A deputation subsequently waited upon the Minister of Health to present to him the above resolutions. In reply the Minister stated that circulars were to be exhibited in public places. The department had also entered into a scheme to supply curative drugs to hospitals throughout the State, and to secure the assistance of all subsidized hospitals. He asked the deputation to put into concrete form its proposals in regard to the formation of a council for combating these diseases, and promised the assistance of the Government in the publicity campaign. He did not pronounce any opinion on the suggested instruction of young persons, though he regarded it as a duty that mothers and fathers could best perform. He advised the deputation to refer the question of the law with regard to prostitution to the Minister for Justice, and the question of sex hygiene to the Minister for Education.

Correspondence.

DR. ADAM'S 'CROONIAN LECTURES.

Sir,—Sir E. Ray Lankester, it appears, falls foul of the term "academic biologist." By labelling a man as "academic" it is in general meant to imply that such a one is more concerned with upholding the teaching and tradition of the Schools than with the advance of his subject. Had I wished to demonstrate to your readers what I meant by this term, I could not possibly have afforded a more perfect instance than, by his letter in your last issue, Sir Ray has himself presented.

Take, for example, his treatment of my use of the term "direct adaptation," ascribed to Spencer, and of my demonstration that this surely exists among the bacteria. Herbert Spencer wrote (*Principles of Biology*, 1898 edition, vol. i, page 528): "There go on in all organisms certain changes of function and structure that are directly consequent on changes in the incident forces—inner changes by which the interchanges are balanced and equilibrium restored. But . . . we see that the modified conditions to which organisms may be adapted by direct equilibration are conditions of certain classes only. Besides direct there must be indirect equilibration." Where is the difference between my "specific modification in response to a specific alteration in environment *within limits to be presently laid down*" (Sir Ray manages to leave out the phrase in italics) and Spencer's "certain changes . . . that are directly consequent," etc.? Later, in the abstract of my second lecture, which was in Sir Ray's hands, it is pointed out that experiments can be so made as to remove all possible question of chance variation and survival of those forms alone which had exhibited variation in a favourable direction (Spencer's indirect equilibration), so "that there was within certain limits direct adaptation in the Spencerian sense, direct equilibration between the organism and its environment." Sir Ray, it will be observed, passes this over in complete silence, and makes no reference to my further

¹ In my fourth lecture. By the closing paragraph of my first, as again by the invitation sent him to be present at the series, Sir Ray was advised that other lectures were to follow in which my theme would be developed, but of this he takes no notice.

demonstration of direct adaptation in the matter of acquirement of pathogenic powers. But by a casuistic mingling of Spencer's statements and his own opinion he implies that I confuse direct and indirect equilibration, and states that I hold the view that mere modification of an organism in response to change of environment is in every case "direct adaptation." This is the method of the academic biologist, not of the seeker after scientific truth.

I freely admit that Sir Ray registers two definite hits. First as to the confusion between "variation" and "variability." The two are distinct, and the use of the latter in the circumstances was inaccurate. It will be observed that the section is headed "The nature of variation." I have before now employed the simile that explosiveness, or explosibility, is one of the properties of nitro-glycerine, but that it requires a force from without to produce an explosion of this body. It would have been more accurate had I written, "whether we deal with an inherent tendency to vary, or a capacity on the part of living matter to be varied." But every fair-minded reader will realize that this was the drift of my argument, and will see that the misuse of the word variability weakened instead of strengthening it. So, also, to those of us who have met Weismann I confess that "vigorously" rather than "violently" would have been the more appropriate adverb. But this again has no bearing on the main argument. His hits are "outers."

As to the other more personal matters in Sir Ray Lankester's letter, these again are all evasions of the main issue, such as a controversialist employs to darken counsel. They turn upon a triangular correspondence between X (an old friend of Sir Ray's), Sir Ray, and myself, in which, at the request of X, I wrote my views upon adaptation to him; X showed my letter to Sir Ray; and Sir Ray's reply, while addressed to me, was forwarded to X to read and send on to me. To quote loyally the sense of a statement is not to "garble" that statement, with what that implies, and I challenge Sir Ray to publish the correspondence in full elsewhere, to show that my reference was not substantially correct, and that I was not justified in my action. My two letters are, and have always been, at his disposal for this purpose.

For myself I desire no German naval victory in which, before the action is fully developed, the fleet returns in triumph to its home port sheltered by a cloud of inky smoke. Nor do hard hits irritate me so long as they are clean. But I do feel most strongly that this matter of adaptation and its mechanism is a matter that is not the possession of zoologists and biologists alone, for them to dream dreams about and hold unseemly parochial wrangles over at meetings of the British Association. It is one in which medical men and the community at large are to-day very immediately concerned, one in which our voice has a right to be heard and our experience to be seriously weighed and considered, instead of being contemptuously spurned as coming from outside the pale; one in which we look for dependable leadership from men of the status of Sir Ray Lankester, and not receiving it must take the lead ourselves. To quote from Herbert Spencer's final words on the subject, "And now I must once more point out that a grave responsibility rests on biologists in respect of the general question (inheritance), since wrong answers lead, among other effects, to wrong beliefs about social affairs and to disastrous social actions. In me this conviction is increasingly strengthened. Though the *Origin of Species* proved to me that the transmission of acquired characters cannot be the sole factor in organic evolution, yet I have never wavered in the belief that it is a factor, and an all-important factor. And I have felt more and more that, since all the higher sciences are dependent on the science of life and must have their conclusions vitiated if a fundamental datum given to them by the teachers of this science is erroneous, it behoves these teachers not to let an erroneous datum pass current."

To understand the full significance of what is here written I would ask my readers to turn to Sir Ray's letter of last week's issue and read it once again.—I am, etc.,

J. G. ADAMI,
Lieut. Colonel, C.A.M.C.

London, W.

* In the Appendix to the last edition of the *Principles of Biology*.

"PRACTICAL METHODS OF ANAESTHESIA."

SIR,—An article by Dr. J. T. Gwathmey¹ contains statements so surprising, and so directly opposed to the conclusions arrived at by me after long experience in the administration of anaesthetics, that I feel constrained to offer some remarks. Dr. Gwathmey says: "Chloroform, anethol, and ethyl chloride are rarely used as the terminal anaesthetic; as the initiatory agent, however, they are most useful." This is true enough of ethyl chloride (I know nothing of "anethol"), but is surely the converse of the truth as regards chloroform. A large number of fatalities under this agent occur in the early stages of anaesthesia; and many of us rightly believe that, whenever possible, it is safer to avoid pure chloroform for the purpose of induction. On the other hand, chloroform is often most useful, almost indispensable, as a "terminal anaesthetic."

"Open drop ether" (presumably open etherization is meant) "is a crude, unscientific method. . . . It is irregular and uneven, and conduces to acidosis and resultant shock, on account of the insufficient supply of oxygen." In reference to these statements, may I ask how an insufficient supply of oxygen can possibly be caused by open ether?

"The gas-ether sequence is an even cruder and more dangerous method. It raises the blood pressure enormously, cyanoses the patient, and is responsible for many deaths." Is this the experience of any anaesthetist familiar with the use of Hewitt's apparatus for the nitrous oxide-ether sequence? To me the whole assertion appears absurdly false. Dr. Gwathmey's next paragraph seems to deal with the same method, which is condemned on account of "automatic suction." What is "automatic suction"? And how does it come into the process? The alternative plan suggested which "removes all the objectionable features" is not explained. Towards the end of the article there is a reference to an undescribed "semi-open method" whereby "the ether-nitrous oxide anaesthetic vapour is warmed, moistened, oxygenated, and deodorized, and the patient neither tastes nor smells the ether at any time." This last result is, of course, obtained by the intelligent use of Hewitt's apparatus.

Dr. Gwathmey throws doubt upon the safety of gas and oxygen, but omits to mention that all the deaths have occurred during or after prolonged administration; for short operations—dental, etc.—for which the method was originally designed, nothing is safer.—I am, etc.,

Eastbourne, April 19th.

H. S. GABBETT, M.D.

A TOO-PUNGENT MOUTH-WASH.

SIR,—Dr. Helen Goodrich's article on "Mouth-washes in health and disease" (*BRITISH MEDICAL JOURNAL*, April 14th, p. 473) calls for a word of caution, inasmuch as she concludes by recommending the daily use in healthy mouths of a saturated aqueous solution of thymol. I venture to predict that if ten people with perfectly healthy and normally sensitive mouths use such a solution of thymol "as often as possible" as Dr. Goodrich suggests, at least eight out of the ten will have marginal gingivitis at the end of three months. In a sensitive mouth it stings like mustard, and is far too pungent for regular daily use. There is little doubt that a large proportion of the many cases of chronic marginal gingivitis (the initial stage of pyorrhoea) is due entirely to the prevalent use of mordant mouth-washes and pastes.

Thymol in saturated solution is an irritant to the oral tissues, and in that strength is not a suitable lotion for habitual use in a healthy mouth.—I am, etc.,

Bournemouth, June 24th.

J. T. HALL, L.D.S.

THE NEED FOR EARLY SANATORIUM TREATMENT.

SIR,—I was in no way astonished on reading Dr. Bardswell's statement in the *BRITISH MEDICAL JOURNAL*, June 9th, that as many as 75 per cent. of cases admitted into the King Edward VII Sanatorium were already in the second or third stage of the disease. I find on looking up our records that our proportion is very similar—about 72 per cent. of cases having passed the first stage.

That Dr. Bardswell is unable to see any improvement

¹ *BRITISH MEDICAL JOURNAL*, March 24th, 1917.

as the years roll by is very disappointing and provides food for thought.

I am of opinion that the following are the chief reasons for this unfortunate state of affairs: (1) The publicity which has been given to the discussion of this disease and the unfortunate terms which have been used, the name "great white plague" is not likely to attract patients in the early stage. (2) The fear of being regarded as infectious deters many from admitting that they are sufferers; thus the means defeats the end. I find it very difficult to persuade some people that a person may suffer from pulmonary tuberculosis and yet not be infectious. (3) The prominence given to after-care schemes destroys in the minds of many the belief that if treated at the proper time after-care, except as indulged in by the patient himself, is unnecessary. (4) Public utterances about the advisability of segregating consumptives by force. This is particularly objectionable at a time when any local authority which is willing to do its duty will find that it has not got sufficient accommodation to segregate the willing. (5) The unwillingness of medical men to explain to patients that they can be cured. It is scarcely worth while to quibble with terms, and to say that pulmonary tuberculosis cannot be cured is only to quibble. Small-pox often leaves scars, but no one says it cannot be cured. If it be remembered that practically all town dwellers have been infected with tuberculosis by the time they reach 20 years of age, it must be clear that cure in the case of such a disease must be rather a question of degree, and it should be our duty to arrange if possible that patients are prevented from reaching that degree of disease which precludes a cure; and patients should certainly not be watched to see whether they will commence to spit tubercle bacilli if they are suffering from the symptoms of active disease.

In order to get patients in a curable stage to go to sanatoriums, as few people as possible should intervene between the patient and his admission. The idea present in the minds of most people is that a sanatorium never cures and therefore a patient is never sent until incurable.

In conclusion, I would suggest that a sanatorium should not be looked upon merely as a means of preventing people from dying, but chiefly as a means of preventing many of the most favourable cases from becoming chronic, by making them discontinue their work for a comparatively short time. At the present time these latter often live for years continuing their work, but often remaining infectious.—I am, etc.,

EDWARD E. PREST.

Ayrshire Sanatorium, New Cumnock,
June 14th.

MEDICAL STUDENTS IN AND OUT OF THE RANKS.

SIR,—I am glad that the question has been raised as to what is going to be done for those medical students who, answering their country's call, gave up their studies and their prospects of early qualification.

My only son, to whom I was looking for relief, accepted a commission in 1914 when in his second year. He has now been on foreign service for over two years, and, providing he is not killed, looks like serving at least two more years. By that time he will be 24 years of age, and will still have four more years before he can qualify, not to speak of the year or two of hospital work before he will be fit to succeed me. Meanwhile those students in his year who, quite as fit as he, but endowed with less patriotic feelings and more concern for their own individual welfare, resisted their country's call, are now enjoying complete immunity from service, together with good hospital appointments as unqualified house-surgeons (at £90 a year), and are within a year of being able to take up practice. One wonders whether patriotism really pays. Still I do not envy them or wish my son had emulated them. I am only anxious to know whether, if my son does ever come back, he will be granted any facilities for shortening the time which he would normally require to complete his course. I scarcely need point to ways by which this could be done, when one remembers the holidays which were the rule in normal times. It only needs some little rearrangement on the part of the university authorities in the matter of these holidays, and the facilities for examination, to reduce the time required by one or even

two years. I trust that we may have an authoritative pronouncement on this matter.—I am, etc.,

July 15th.

J. A. A.

PART-TIME CIVIL SURGEONS.

SIR,—Colonel Galloway's very handsome tribute to the work of part-time civil surgeons employed in the examination of recruits will be much appreciated and might well be extended to those who have undertaken work in military hospitals.

Here, too, the duty undertaken has been purely patriotic and the rate of pay quite inadequate. The part-time civil surgeon is nearly always employed in a subordinate capacity, often the work expected of him cannot, under any conditions, be said to come within the terms of his employment, and he is subjected to those irritating and petty annoyances which are unknown in a civil hospital.—I am, etc.,

Catherham, July 15th.

G. A. CLARKSON, F.R.C.S.

PAYMENT OF MEDICAL OFFICERS TO V.A.D. HOSPITALS.

SIR.—The question of the payment of medical officers to V.A.D. hospitals is to come before the Annual Representative Meeting next week. I opine that few, if any, of the medical officers concerned would wish to receive any payment for their services. But I would suggest that they allow the money to be collected by some central body—for example, the British Medical Association, or the Royal Medical Benevolent Fund, in order to form a fund for the help of the families or dependants of those members of our profession who have lost their lives or health while on active service. Such a fund is likely to prove very useful at the end of the war.—I am, etc.,

Bolton, July 16th.

R. D. MOTHERSOLE.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE following candidates have been approved at the examinations indicated:

SECOND B.M.—*Materia Medica and Pharmacology*: T. A. Brown, E. H. Claver, J. C. Dixey, R. Gainsborough, C. F. Krige, J. E. B. Morton, A. E. Thomas. *Pathology*: H. G. Burford, J. C. Dixey, F. B. Dutton, J. E. B. Morton, H. W. Toms, B. Tordoff, K. F. D. Waters. *Forensic Medicine and Public Health*: J. J. Conybeare, G. R. Cowie, E. A. Crook, F. B. Dutton, W. F. Harvey, R. M. Humphreys, R. W. Lush, J. J. Savage, J. P. S. Walker. *Medicine, Surgery and Midwifery*: J. J. Conybeare, G. R. Cowie, E. A. Crook, W. F. Harvey, R. W. Lush, J. P. S. Walker.

UNIVERSITY OF CAMBRIDGE.

THE following medical degrees were conferred at a Congregation on July 13th:

M.D.—G. A. Lilly, N. Mutch.
B.C.—A. R. Jennings.

UNIVERSITY OF LONDON.

At a meeting of the Senate on June 20th Mr. C. H. S. Webb and Mr. W. Sampson Handley were recognized as teachers of surgery at the Middlesex Hospital Medical School, and Dr. Charles Bolton was appointed acting director of the Graham Research Laboratory in the absence on military service of Dr. Boycott.

UNIVERSITY OF BRISTOL.

THE following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B. (*Part I only*).—Evelyn B. Salter.
D.P.H. (*Part II, completing examination*): I. B. Barclay. (*Part II only*): H. J. Drew-Smythe.

UNIVERSITY OF EDINBURGH.

GRADUATION CEREMONY.

A GRADUATION ceremony in medicine, arts, and science took place in the McEwan Hall of the University on July 11th. The Principal presided, and Dr. W. Russell, professor of clinical medicine and President of the Royal College of Physicians, gave an address on "The need of the future: efficiency based on moral responsibility." The great aim and purpose of undergraduate days, he said, was not to pass examinations, however important as a test they might be, but to be fitted to become true students and observers of the reactions and contests of the human body against injurious domestic influences as well as against obnoxious alien forces. The task of the new graduates was to cultivate the faculty of sound judgement; that truth

was expressed in the phrase, "With all thy getting get understanding" in the Book of Wisdom, and had been embodied by a poet laureate in the words "Knowledge comes, but wisdom lingers." Some of them would at once have to take their places in armed camps; others would have to do the work of men called to those camps, but individually they could best serve their country and the great cause for which the world was suffering and fighting by cultivating personal efficiency. Opportunity came to the man who used well the material about his hands. The mind of men and women were turning anxiously to the contemplation of after-war conditions, but though prevision was given to few it would be safe to prophesy that human nature would not be radically altered. It could hardly be hoped that the false prophet, the facile-tongued charlatan not unknown even in medicine, the narrow specialist, and the faddist who never learnt that truth was a bigger thing than the gnat which filled his eye, could be got rid of. Still some pre-war points of view would be got rid of, and others established. There would be regroupings and rearrangements, a new earnestness, less selfishness, and a widened sense of service for the commonwealth.

Later in the day a commemorative service was held in St. Giles's Cathedral, when the Rev. Dr. Galloway, Principal of St. Mary's College, St. Andrews, preached.

The following are the successful candidates:

- M.D.—F. O. Clarke, W. J. Crow, F. B. Dreyer, P. W. MacLagan, J. G. O. Moses.
M.B., B.S.—G. G. Allan, J. G. Allan, L. G. Allan, R. Andrew, J. S. Bow, Sarah Boyd, W. W. Brown, W. D. Brunton, J. C. Burns, W. E. Canekerate, Ba Than Chain, Fakir Chand, Datta Pares Chandra, T. S. Duncan, H. B. Dykes, P. B. Eaton, W. Everett, N. P. R. Galloway, Aja Singh Garewal, J. B. Kirk, J. L. Lamont, D. McEachran, Annie M. Mackay, W. D. Mackinnon, D. W. McLean, H. R. Mailer, A. R. Matheson, R. A. Nathaniel, J. MacR. S. Nichol, R. D. Osler, A. van der Poel, F. W. Poole, C. B. B. Reid, H. B. Renton, S. S. Rosebery, A. O. Ross, J. H. M. Sandison, J. Schneider, J. M. H. Smellie, G. L. M. Smith, J. O. P. Smith, Janet Smith, J. H. R. Smith, S. L. Smith, A. Strachan, Ying Kwan To, J. M. Tyrrell, L. Walker, W. A. Weatherhead, J. D. White, J. Wolfson, A. T. Woodward.

- * Awarded gold medal for thesis.
† Passed with first class honours.
‡ Passed with second class honours.

The following scholarships and prizes have been awarded: Ettles Scholarship, Beane Prize in Anatomy and Surgery, and the James Scott Scholarship in Midwifery: R. Mailer. Mout Scholarship in the Practice of Physic: L. G. Allan. Conan Doyle Prize: J. E. Hurworth. Scottish Association for Medical Education of Women Prize and the Dorothy Gilfillan Memorial Prize: Susan A. Robertson. Cunningham Memorial Medal and Prize in Anatomy: A. J. C. Hamilton. Whiteside Bruce Bursary: W. M. Robb.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At a quarterly council meeting on July 12th Sir George Makins, K.C.M.G., C.B., Surgeon-General (temporary) A.M.S., was elected President in succession to Sir W. Watson Cheyne, who had held that office since 1914. Mr. Charters J. Symonds and Mr. William F. Haslam were elected Vice-Presidents.

The President was elected a member of the Committee of Reference under the Military Service Acts.

CONJOINT BOARD IN SCOTLAND.

The following candidates have been approved at the examinations indicated:

FINAL EXAMINATION.—J. F. Campbell, J. H. Brown, F. M. H. Sanderson, W. U. D. Longford, H. E. C. Collins, D. McG. Stewart, Mung Sun Low, A. G. Bee, F. Jones, Eliza J. Stewart, D. C. McNair, C. J. Middleton. (*Medicine*): Indranarayan Borrah, G. P. de Silva, C. R. C. Moon. (*Surgery*): I. Davies. (*Midwifery*): B. M. Lynam, G. P. de Silva. (*Medical Jurisprudence*): I. Davies, J. D. Begley, J. A. A. Duncan, A. H. B. Hudson, A. S. Hughes, Rebecca Goodman, Hassan Amin Madwar, Q. Stewart, C. C. Magee.

CONJOINT BOARD IN IRELAND.

The following candidates have been approved at the examinations indicated:

FINAL EXAMINATION.—H. G. P. Armitage, J. J. Campbell, T. Curran, J. B. Dwyer, P. J. Flood, H. W. Hackett, J. Harvey, J. Hegarty, J. E. Lucas, T. J. Lynch, E. McCarthy, T. P. MacDonnell, F. J. Power, J. F. Seale, D. J. Steele, R. T. Stoney.

The London County Council is establishing a school treatment centre at Balliol House, Whitechapel, for the treatment of 1,540 dental cases and 660 minor ailments cases a year, and a dental and minor ailments centre in Bethnal Green.

The *New York Medical Journal* states that a recent investigation made by the United States Public Health Service in connexion with studies of school children in rural districts showed that 49.3 per cent. of the children examined had defective teeth, 21.1 per cent. had two or more teeth missing, and only 16.9 had had dental treatment. Over 14 per cent. never used a toothbrush, 58.2 per cent. used one occasionally, and only 27.4 per cent. did so daily.

Obituary.

MAJOR WILLIAM GUTHRIE PORTER, R.F.A.(TER),
D.S.O., B.Sc., Ch.B., F.R.C.S.(Ed.),
EDINBURGH.

On June 8th, while going forward to find a suitable position for the battery he commanded, Major Porter was shot by a German sniper.

Porter was well known as a rising specialist. In 1912 he produced an excellent textbook on *Diseases of the Throat, Nose, and Ear*, written with a view to meeting the requirements of the general practitioner. In the same year he and Dr. Logan Turner brought out their joint work on the *Skiagraphy of the Accessory Nasal Sinuses*. In addition, Porter contributed the article on "General therapeutics of diseases of the ear" to Allbutt and Rolleston's *System of Medicine*, and papers on the "Treatment of laryngeal tumours," "Resection of the nasal septum," "On a fold sometimes found in front of the posterior nasal opening," and "Nystagmus of the right vocal cord and soft palate in a case of cerebral disease." At the time of his death he was surgeon to the Eye, Ear, and Throat Infirmary (Edinburgh) and to the Ear and Throat Department of the Royal Hospital for Sick Children, and aurist to the Edinburgh Royal Institution for Education of the Deaf and Dumb.

He was a man of unusual ability, a hard worker, a brilliant operator, and a conscientious observer, so that had he lived a few years longer there can be little doubt that he would have been among the foremost oto-laryngologists of the country.

In early manhood he was a well-known football player, but of late years such holidays as he allowed himself were spent in camp with Territorial artillery, of which he was an enthusiastic officer. When war broke out Porter gave up his medical work and became permanently a combatant. The writer had heard from friends who returned from France on leave how absolutely fearless he was, and letters received after his death from both officers and men testify to his great courage, while the latter also bear witness to his kindness of heart and consideration for others. All these things those of us who were privileged to enjoy his friendship knew—and more. We knew, for instance, his lovable nature, his high code of honour, his unselfishness, and his modesty, for while extremely self-reliant, he never seemed conscious that he possessed unusual ability. That he did more than ordinarily well as an artillery officer is shown by the fact that during the war he rose to the rank of major, was mentioned in dispatches, and received the D.S.O. When Porter died there passed away a distinguished specialist who was at the same time not only a gallant but also a distinguished soldier.

DR. JAMES USHER HUXLEY died at Oxford on his 83rd birthday on June 24th. After serving an apprenticeship under Dr. Bell of Rochester he entered King's College, where he had a distinguished career. He took the diplomas of M.R.C.S. and L.S.A. in 1860, and graduated M.D.Lond. in 1864. He served on the staff of the Exeter Hospital for seven years and then removed to Torquay, where he practised for forty years. He retired from practice on reaching the age of 75. He was a collector of china and works of art. In 1882 he married the eldest daughter of Sir Benjamin Collins Brodie, who, together with five daughters, survive him.

DR. THOMAS SHELDON died at his residence in Powis Square, W., on June 20th, in his 83rd year. He was the eldest son of William Sheldon, J.P., of Stratford-on-Avon. He studied medicine at University College Hospital and the University of Edinburgh, qualifying M.R.C.S. in 1859, and taking his M.D. degree in 1863. He was in the same year at Edinburgh as Joseph Bell and Argyll Robertson. After qualifying he served as resident physician at the Edinburgh Royal Infirmary under Dr. Warburton Begbie. For fifty-four years he practised in Kensington, where he was well known and greatly respected. He was the first medical officer to the Kensington Division of the Post Office, and held this post for thirty years. Dr. Sheldon took great interest in his duties at Justice of the Peace for the County of London. He married Elizabeth Anne,

daughter of Peter Pearse, a well-known city solicitor, and had three sons and two daughters. One son is a fleet surgeon, R.N., and another, who followed his father in practice, is a temporary lieutenant in the R.A.M.C.

DR. CHARLES CARTER SHEPHERD, who died recently at Cardiff, was born at Barbados and received his medical education at St. Bartholomew's Hospital and the University of Aberdeen. He graduated M.B., C.M.Aberd. in 1879, and M.D. in 1890. He had been in practice at Cardiff since 1891, was a member of the Cardiff Division of the British Medical Association and of the Cardiff Medical Society. He leaves a widow and eight children.

The death is announced of Dr. W. AWUNOR RENNER of Freetown, Sierra Leone. He studied at University College, London, and at Liverpool and Brussels. He took the diplomas of M.R.C.S.Eng., L.R.C.P.I. and L.M. in 1880, and the M.D.Brux. in the following year. He became an assistant in midwifery to Professor Briggs of the University of Liverpool, and also assistant in surgery to Professor Rushton Parker, and worked under the late Sir William Mitchell Banks. Dr. Renner was in the Government service of Sierra Leone for over twenty-nine years. After serving at first as assistant colonial surgeon, he, on the formation of the West African Medical Service, became P.M.O., and was commended by the late Mr. Joseph Chamberlain, then Secretary of State for the Colonies, for the manner in which he carried out his duties. Dr. Renner retired from the Government service in 1913 and devoted himself to public affairs. He was appointed a councillor, and in November, 1916, mayor, of Freetown, which position he held at the time of his death.

Medical News.

SIR ROBERT ARMSTRONG-JONES has been placed upon the Commission of the Peace for the County of London.

DR. L. A. TAYLOR, Honorary Secretary of the Dudley Division of the British Medical Association, and Dr. J. Reidy, a member of the Stepney Borough Council, have been appointed to the Commission of the Peace for the County of Stafford and the County of London respectively.

It has been brought to the notice of the Ministry of Pensions that a number of pensioners are appealing to the charitable on the ground of insufficient means. The Local War Pensions Committee, whose address is obtainable from the nearest Post Office, have ample powers for dealing with all deserving cases of this nature from public funds, and the charitable public are therefore urged to refer such applicants to this body.

THE Imperial Nurses Club, 137, Ebury Street, London, S.W.1, was opened last November by Lord French. It forms a resting-place for members of the military and civil nursing profession passing through London. It has been of special value to those proceeding to or from active service abroad. Funds are needed to place the club on a firm footing, and donations may be sent to the honorary secretary.

THE annual meeting of the Medico-Psychological Association of Great Britain and Ireland will be held at 11, Chandos Street, Cavendish Square, London, on Wednesday, July 25th, at 2.45 p.m., under the presidency of Lieut.-Colonel David G. Thomson, M.D., when the usual reports will be presented and the regulations and syllabus for the training and examination of candidates for the certificate of proficiency in nursing and attending on the mentally defective will be considered. A paper by Dr. Mercier on madness and unsoundness of mind will be read for him by Sir Bryan Donkin.

SIR A. GARROD THOMAS, M.D., of Newport, has been elected to represent South Monmouth in the House of Commons by a majority of 6,042, which is the largest on record. Sir Garrod Thomas stood in support of the Government. He is an ex-president of the South Wales and Monmouthshire Branch of the British Medical Association, and was vice-president of the Section of Diseases of Children when the Association held its annual meeting in Swansea in 1903.

THE *Dictionary of National Biography* has been presented to the University of Oxford by the family of the late Mr. George M. Smith, and will in future be published

by the Oxford University Press. Mr. George M. Smith undertook the great work at his sole risk and expense in 1882; during fifteen and a half years, 1885-1900, under the editorship of Sir Leslie Stephen and Sir Sidney Lee, the original promise of quarterly publication was faithfully kept; the sixty-third volume, which completed the *Dictionary*, was published in 1900, and three volumes of supplement, bringing the record down to the death of Queen Victoria, were published in 1901; Mr. George M. Smith died on April 6th in that year. In 1908-9 these sixty-six volumes were reissued in twenty-two volumes, now the current edition. In 1912 Mrs. George M. Smith, to whom the *Dictionary* had been bequeathed, published the second supplement of three volumes, containing the lives of all notable persons who died between January 22nd, 1901, and December 31st, 1911.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

THE telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are: (1) EDITOR of the *BRITISH MEDICAL JOURNAL*, *Aitillogon*, Westrand London; telephone, 2531, Gerrard. (2) FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand London; telephone, 2530, Gerrard. (3) MEDICAL SECRETARY, *Medisecra*, Westrand London; telephone, 2534, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

LETTERS, NOTES, ETC.

A STATE MEDICAL SERVICE.

DR. FERDINAND REES (Wigan) writes: From the article on a State Medical Service in your last issue one must infer that the British Medical Association considers it its duty to tackle the advocates of a State medical service wherever they may venture to appear. The medical profession has always been very Conservative in its ideas, probably because the majority of its wealthy customers have belonged to that political party. The aim of the keen medical shopkeeper has always been never to offend his wealthy customers. The majority of the medical profession have always been the flunkies of the wealthy. The squire, the parson, and the doctor have always run in harness; but the squire has always determined the direction and the pace. Dr. Brackenbury (the champion of the British Medical Association) has an epigram about treating men, women, and children which reminds one of the advice, which the successful medical tradesman is so fond of giving to the young practitioner, "Treat the patient." Keep the patient on your visiting list as long as possible and run up as big a bill as possible. Of course there may be some tradesmen who make big incomes by "small profits and quick returns." Some sixpenny doctors have been most successful from the monetary point of view. The Robin Hood maxim of robbing the rich to give to the poor has been very popular with some practitioners. To be the amuser of fashionable ladies has proved very lucrative to other practitioners. No wonder that Christian Scientists and quacks flourish! Is disease a reality? Is scientific medicine a myth? From the way the Brackenburys talk one would imagine that every one nowadays had free choice of doctor. Why is the specialist so increasingly popular? Is the present method of remuneration essential to the happiness of patient and doctor? Would not the community obtain more efficient doctoring if there were collective action against disease? Why should the doctor be bothered with bills and book-keeping and a study of the arts of trade and advertisement? Let your champion deal with a few of these questions.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 6 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postae restant* letters addressed either in initials or numbers.

TROPICAL MEDICINE AND HYGIENE.

BY

SIR PATRICK MANSON, G.C.M.G., F.R.S.,

LATE MEDICAL ADVISER TO THE COLONIAL OFFICE.

It has long been recognized that a number of diseases are peculiar to, if not confined to, warm climates. Many hypotheses in explanation of this circumstance have been advanced, but it is only of late years—only since we have been able to recognize the germ causes of many of these diseases, or the media by or in which they are conveyed—that it has become possible to arrive at the true explanation. Almost without exception, tropical diseases—that is to say, those diseases which require for their successful propagation a warm climate—are caused either by a protozoal organism or by a helminth, which, in their turn, in order to pass from one vertebrate host to another, demand either an animal vector peculiar to warm climates, or require a warm medium in which to qualify for such passage. Hence, although tropical disease once acquired can run its usual course even if the person remove to a cold or even frigid climate, that person cannot spread the disease there, nor, under natural conditions, can the disease be acquired there. On the other hand, bacterial diseases may be acquired and spread in any climate, as the germs in their passage from one human host to another do not necessarily demand any special animal intermediary, nor are they destroyed in their passage by ordinary temperatures. In the following summary relating to British contributions to tropical medicine bacterial diseases are therefore not considered. It is true such bacterial diseases as leprosy, cholera, and plague are often referred to as tropical diseases, but a little consideration—a little investigation into their history and geographical range—will show that they have no more claim to be considered tropical diseases than have tuberculosis or syphilis.

MALARIA.

Although a number of contributions of considerable importance in tropical pathology had been made by British as well as by other investigators prior to 1880 there can be no question that it was the discovery by Laveran of the malarial parasite, in the November of that year, that has led to the recent rapid and remarkable development in tropical medicine. It was some time before the value of Laveran's discovery was recognized, or the nature of the organism concerned and the significance of its various phases determined. Golgi made an important advance in these respects by working out the morphological features of the tertian and quartan parasites, and of what is now known as the schizogony or asexual phase. Further advances in our knowledge of this part of the life-cycle of the malarial parasites were also made by other Italian observers; but here, for the time being, progress ceased. It may therefore be said that, except as providing an invaluable guide in diagnosis and treatment, Laveran's discovery for more than a decade remained barren. It gave no clue to prevention; it did not tell us in what way malarial infection was acquired, nor did it explain its peculiar geographical and topical distribution and limitation.

As the development towards sexual maturity—a biological necessity for the malaria parasite as for all animal parasites—had never been traced in the human body, it follows that to effect this necessary development escape from the human body is essential. Neither Laveran nor Golgi's observations had filled in this important gap in the life-history of the parasite.

Golgi, it is true, had made out the significance of certain phases of the parasite as seen in the circulation; he showed in what way the invading organism multiplied after it had obtained entrance into the human body, but neither he, nor any of his co-workers, had grasped the significance of certain additional phases also represented in the blood, and more especially manifested on the microscope slip—that is to say, in blood after its removal from the human body.

Perhaps the most striking feature in connexion with the malarial parasite as observed under the microscope is the so-called "flagellated body." This squirming, wriggling, many-armed organism had long been a puzzle to the naturalist as well as to the pathologist. Some got over the

difficulties of its explanation by pronouncing it to be a moribund or effete form of the parasite in its death agony. It had been observed that this flagellated body shows itself only in blood that had been for some time on the microscope slip—that is to say, after the parasite had been removed from the human body. It had never been seen in quite newly-drawn blood. Its development had been witnessed over and over again from certain intracorporeal forms of the parasite, but only after the blood containing these forms had been in the field of the microscope for a considerable period. This fact of the flagellated body coming into existence as such only when the parasite from which it was evolved had left the human body suggested to the writer that its function lay outside the human body, and, if so, that it was the early extracorporeal phase of the parasite and, if we may use the expression, designed for its passage from one human host to another. But, assuming that such was the case, it remained to explain how an organism, which while still in the body was invariably included in a red blood cell, could spontaneously and by its own efforts escape from the human body. Such a feat on the part of a passive organism was inexplicable. I was driven to the conclusion that if this phase of the malarial parasite were really the first stage in its development outside the human body some extraneous agency must act as liberator. The question then came to be what this extraneous agency might be.

Many years before the writer had shown that in the case of another blood parasite—*Filaria bancrofti* (the *Filaria sanguinis hominis* of Lewis)—the mosquito acted as a liberating and also as a fostering agent. Impressed by the close parallelism, as regards their respective physical conditions and necessities, between the malaria parasite and the filaria—the one being imprisoned in a blood corpuscle and powerless to escape, the other, the sheath-included and equally helpless filaria—as well as their respective biological necessities, he thought that the same, or a similar liberating agency might be operative in both instances. An additional circumstance pointing to such a hypothesis was that both parasites are limited in geographical range to warm climates. On these considerations it was concluded that as the mosquito had been proved to be the liberating agent in the case of the filaria, it might be, and probably was, the liberating agent in the case of the malarial parasite, and therefore that the first phase of the malarial parasite outside the human body had to be passed in this insect. I formulated this hypothesis in the BRITISH MEDICAL JOURNAL of December 8th, 1894. Unfortunately, circumstances made it impossible for me to follow up the fate of the flagellated body in the mosquito, but Sir Ronald Ross, who was then in England, was so impressed with the probability of my hypothesis being correct, that on his return to India in 1895 he set to work to endeavour to establish it. After many years of intense application and in the face of many difficulties, he succeeded in tracing the malarial parasite into the stomach wall of certain "dapple-winged" (*Anopheles*) mosquitoes. In consequence of difficulties in procuring material and suitable human subjects for observation and experiment, he transferred his attention to a malaria-like parasite (*proteosoma*) of birds. In these he succeeded in tracing the development of the parasite in the stomach wall of *Culex* mosquitoes, and thence into the salivary glands and saliva of the insects, and by experiment showed that such insects were capable of conveying the infection to hitherto immune birds. Ross's observations were quickly confirmed by Daniels, Christophers and Stephens, Grassi, and many others. Grassi recognized Ross's "dapple-winged" mosquito as belonging to the *anopheles*-lines, and showed conclusively that certain members of this family of mosquitoes were efficient transmitters of malaria. Ross had not ascertained what exactly happened to the malarial parasite immediately after ingestion by the mosquito, and while still in the lumen of the insect's stomach, which enabled it to pass into the tissues of the stomach wall. An American observer—Macallum—filled in this gap. He showed that the flagellated body of halteridium, another malaria-like parasite of birds, was the male parasite, that the flagella it produced functioned as spermatozoa, that when they broke away in the blood in the stomach of the mosquito they entered a female parasite, inducing therein a development that eventuated, while the female was still in the stomach

of the insect, in the formation of that "travelling vermicle," which penetrated the stomach wall and therein entered on the development Ross had so successfully traced. Thus was completed the history of the life-cycle of the malarial parasite outside the human body, confirming the mosquito-malaria hypothesis.

Although the work of Laveran and Ross was accepted by those best competent to judge, and although the direction in which its principal application should be made was evident to all well-informed tropical sanitarians, the public was by no means convinced of its reliability or of the importance of the mosquito as a diffusing agent of malaria. Experiments on human beings had succeeded in the hands of the Italians in demonstrating that a mosquito fed upon a malarial patient could, after an interval of ten to twelve days, convey malaria to hitherto immune individuals, but the public did not appreciate this, and moreover, as the experiments had been conducted in malarious countries there was always a possibility that some unsuspected fallacy associated with locality had crept in, seeing that other influences which might include the true malaria influence were possibly operative. Accordingly, the British Colonial Office, believing in and recognizing the importance of the discoveries as bearing on the health and prosperity of tropical countries, devised an experiment designed to convert the public to the mosquito-malaria theory and to facilitate in this way practical measures based on that theory. In 1900 it sent to the Roman Campagna an expedition consisting of Drs. Sambon and Low, of the London School of Tropical Medicine (who were subsequently joined by an artist), with instructions to live in a mosquito-protected hut located in a highly malarious district of that highly malarious region during the most malarious season of the year, protected at night only, and by wire gauze covering only, from mosquito attack. Although the people about them were heavily affected with malaria these observers, relying solely on mosquito protection, remained in perfect health. At the same time mosquitos infected in Rome with malarial parasites were sent to London by the same observers, and were there fed on two Englishmen who had never been exposed to malarial influences, or been in malarious countries, with the result that both these men contracted malarial fever and showed malarial parasites in abundance in their blood. This crucial experiment was accepted by the most sceptical as conclusive proof of the mosquito-malaria theory.

It was long before Laveran's discovery was appreciated in England, but it made way by degrees, and its significance and importance became thoroughly apprehended by a few. It may be said that it led more or less directly to the establishment, at the instance of the late Mr. Joseph Chamberlain, of our schools of tropical medicine, wherein large numbers of post-graduate students destined for service in tropical countries were taught haematology and the study of the blood parasites generally. These students, well taught in blood examination with high powers of the microscope, were, as a result of this training, not only more efficient practitioners but before long were instrumental in discovering other pathogenic organisms of importance in tropical pathology. Some of these discoveries may be referred to.

TRYPANOSOMIASIS.

Forde, a former student of the London School of Tropical Medicine, found in the blood of an Englishman living in the Gambia and suffering from an irregular fever an organism the nature of which he failed to recognize. He showed it to Dutton, an emissary of the Liverpool School of Tropical Medicine, who recognized it to be a trypanosome, and named it *Trypanosoma gambiense*. Later, Castellani, also a former student of the London School of Tropical Medicine and at the time a member of the Royal Society's Commission for the study of sleeping sickness in Uganda, found the same parasite in the cerebro-spinal fluid of patients suffering from sleeping sickness. Sir David Bruce, Nabarro, and many others confirmed Castellani's observation, and definitely linked up the trypanosome of Forde and Dutton with sleeping sickness as cause and effect. The parasite having been discovered and its association with sleeping sickness confirmed, it became a matter of importance to ascertain in what way the infection was conveyed. Just as happened in the case of the malarial parasite, some

antecedent observations led to the clearing up of this point. Many years before Forde and Dutton's discovery Lewis described a similar organism (*Trypanosoma lewisi*) as a frequent parasite in the blood of the rat. Apparently this parasite of the rat was non-pathogenic. Not long afterwards Evans found a similar parasite in the blood of equines, bovines, and other domestic animals, in association with, and as the undoubted cause of, the deadly disease known in India as "surra."

In 1894 Sir David Bruce investigated in Zululand the disease known in South Africa as "fly disease," an epizootic extensively prevalent among and fatal to domestic animals in South Africa and other parts of that continent, and therefore of great economic importance. He very soon found a trypanosome (*Trypanosoma brucei*) in the blood of the stricken animals and also in the wild game of the infected districts, and confirmed the popular belief that the disease was conveyed by the bite of the tsetse fly—*Glossina morsitans*—one of several species belonging to a genus of biting flies peculiar to Africa.

In the light of this antecedent knowledge it was not long before Bruce and his colleagues in Uganda were able definitely to link up sleeping sickness and its parasite with another species of tsetse fly, *Glossina palpalis*, very prevalent in the afflicted sleeping sickness areas. Observations on the topical distribution of the fly and of sleeping sickness confirmed the conclusions arrived at by experiment on the lower animals—some of which were found to be susceptible to the infection, and to be harbourers of the parasite even under natural conditions.

Bruce at first supposed that the fly transferred the trypanosome directly and in a mechanical way on its blood-fouled proboscis from the infected to the uninfected, just as the lancet inoculates the vaccine virus; but a German (Kleine) showed that although such might be the case in a small proportion of instances, and for a short time—twenty-four hours—after the fly had bitten, in the majority of cases the parasite was conveyed only after it had undergone developmental changes in the fly—changes which require some eighteen days to complete, and which eventuate in a proportion of flies becoming permanently infective. Miss Muriel Robertson, who had previously made important contributions in the morphology and life-history of the trypanosomes of some of the lower animals, confirmed Kleine's observations, and also considerably expanded them by showing that it was only during a particular period in the recurring cyclical multiplication of the trypanosome in the circulation of the vertebrate host that it could be efficiently conveyed to its intermediary the tsetse fly. Further, this talented protozoologist traced the development of the parasite in this insect through its various phases in its passage from the alimentary canal to the salivary glands and thence to the vertebrate. Concurrently with investigations into the life-history of the trypanosome others were directed to ascertaining the topical distribution and bionomics of *Glossina palpalis*, notably by Hodges and Bagshawe.

For some time it was believed that man was subject to only one of the considerable number of trypanosomes now known to affect the vertebrates, but recent discoveries have shown that he is subject to invasion by at least two other members of the group equally, if not more, dangerous—namely, *Trypanosoma cruzi*, an American species which so far has not been studied specially by British observers, and *Trypanosoma rhodesiense*. The discovery of this latter trypanosome we owe to Stephens and Fautham. It appears to be confined to Rhodesia, particularly, but not entirely, to the north of the Zambesi. Morphologically it resembles *Trypanosoma brucei*, if it be not identical with that trypanosome, and like *Trypanosoma brucei* is transmitted, as shown by Kinghorn and Yorke and others, by *Glossina morsitans*.

Much attention has been given by British workers to the symptomatology and morbid anatomy of sleeping sickness. As regards the latter, the most important observations are those of Mott, who has shown that the nervous symptoms of the disease are the result of an extensive small-cell infiltration of the perivascular connective tissue of the brain, very similar to that occurring in general paralysis of the insane.

TICK FEVER.

Vandyke Carter was the first to describe a spirochaete in association with the relapsing fever of India, a spiro-

chaete possibly identical with the *Spirochaeta recurrentis* of Obermeyer. According to Mackie, it is transmitted in India by the louse. Livingstone and Sir John Kirk had called attention many years ago to a fever prevalent in particular parts of Portuguese East Africa (notably Tele on the Zambesi) which was attributed locally to the bite of the carrapata, a tick having bug-like habits. It was reserved for Milne and Ross in Uganda and Dutton and Todd on the Congo to show that this African carrapata disease is a relapsing fever, and that it is caused by a spirochaete—*Spirochaeta duttoni*—which, in its turn, is transmitted from man to man by the bite of the tick *Ornithodoros moubata*; and, further, that it can be transmitted not only by the tick originally infected but also by the progeny of that particular tick. At first there was some doubt as to whether or not the new spirochaete was identical with that of Obermeyer, but well marked differences in their respective pathological and clinical effects on man, as well as the experimental work of Kinghorn and Breinl, showed that, although morphologically similar, they were specifically distinct. The life-history of the spirochaete in the vertebrate host has been worked out to some extent, particularly by Breinl, of the Liverpool School of Tropical Medicine, and in the tick by Sir William Leishman, R.A.M.C. According to Breinl, the parasites, when they disappear from the blood at the crisis of the characteristic recurring febrile paroxysms, are taken up and destroyed for the most part by the phagocytes; a proportion, however, enter certain cells wherein they coil up and, ultimately, after breaking up into a number of granules, escape as such from the cell and develop in the blood into the spirochaetes which, on maturing, give rise to the succeeding paroxysm of fever. As regards the spirochaetes in the tick, Leishman found that on entering the stomach they also break up into minute granules, which pass into the cells of the Malpighian tubes, and thence into the eggs of the tick, and also into its excreta. Thus the parasite has double opportunity of survival, either in the next generation of ticks or by passing out in the excreta of the tick and so obtaining access to a human or other vertebrate host through contamination of the wound it inflicts when the tick next proceeds to feed. Balfour has made some very interesting observations on the process of granule formation and discharge in the case of a similar spirochaete in Sudanese fowls, which tend to throw light on what occurs in *Spirochaeta duttoni*, both in the tick and in the human body.

YAWS.

Soon after the discovery of the spirochaete of syphilis by Schaudinn, Castellani, then of the Ceylon Medical Service, described a similar though different organism, *Spirochaeta pertenuis* (v. *pallidula*) as the germ cause of yaws. His observations have been confirmed and are now generally accepted. The same observer described another species of spirochaete, *Spirochaeta bronchialis*, as the cause of a form of chronic bronchitis occurring in Ceylon, and probably in Africa.

LEISHMANIASIS.

Medical men in India and elsewhere have long been familiar with a form of chronic irregular fever associated with great enlargement of the spleen and liver. It is a deadly disease. In parts of India—Assam, for example—where it is especially prevalent and is called kala-azar, it is a serious matter, having swept away a large part of the population of some districts, and is, or was, spreading steadily as an epidemic over a large part of the Brahmaputra valley. The disease was generally relegated to the malarial group, although some observers, being struck with the absence in this febrile splenomegaly of the three pathognomonic marks of malaria—namely, tertian or quartan periodicity, amenability to treatment with quinine, and the presence of the malarial parasite or its product, haemozoin, in the blood—refused to acknowledge its malarial nature. Several commissions sent by the Government in India to ascertain the exact nature of the disease completely failed to establish its etiology. Some of us thought that kala-azar might possibly be due to some parasite similar to the trypanosome, at that time recently discovered in association with a chronic irregular fever and sleeping sickness. Sir William Leishman in 1902, and again in 1903, almost simultaneously with Donovan, found in the spleen, in cases of Indian febrile splenomegaly, a minute

oval body possessing two nuclear masses, one spherical or oval and relatively of considerable size, the other linear or bacilliform and very minute. Extended investigations have shown that these oval bodies are present in the spleen, liver, bone marrow, and elsewhere in every case of kala-azar, and that they are characteristic and the cause of this deadly disease, which, as we now know, is by no means confined to India. Attempts at cultivation on bacteriological lines, that is to say in warm media, were unsuccessful. Later, however (in 1904), Sir Leonard Rogers ascertained that if these Leishman-Donovan bodies, as they came to be called, were kept at ordinary tropical atmospheric temperatures, about 22° Centigrade, in a sodium citrate solution, they underwent a remarkable development, first multiplying by division and later on developing into flagellated herpetomonas forms. This discovery indicated that the parasite is capable of living outside the human body, it may be in some cold-blooded animal, such as an insect or other intermediary. From the point of view of prevention, it is extremely important that the life-history of *Leishmania donovani* be completed. In endeavouring to attain this desirable end workers must not allow themselves to be too much obsessed by the fact that in the similar parasites of malaria, of trypanosomiasis, of spirochaetosis, as well as those of yellow fever and of dengue, an arthropod intermediary is essential in their life-history. Possibly *Leishmania* requires such a vector and intermediary; analogy certainly suggests this, but suggestion is not proof. The recent, and to my mind very important, observations of Laveran and Fantham and Porter have shown that similar flagellated organisms—proper to insects, etc.—can be transmitted both by inoculation and by the mouth to warm-blooded vertebrates and flourish in them, such transmission being by no means in every instance a biological necessity for these parasites. It is true that Patton has succeeded in tracing the development of *Leishmania donovani* up to a point in the bed-bug, but so far his observations have not been accepted as conclusive that the bug is the transmitter or a necessary agent in the life-history of *Leishmania*.

Not long after the discovery of the Leishman-Donovan body in kala-azar similar parasites were found by Wright in Oriental sore, of which troublesome form of ulceration they are undoubtedly the germ cause. Still more recently similar bodies have been found in a variety of other ulcerative affections in tropical America and, by Christopherson, in the Sudan, one of them, *Espundia*, being a very grave disease indeed.

YELLOW FEVER AND DENGUE.

There are two fevers peculiar to warm climates which, though differing very much as regards gravity, have in some respects, both etiologically and clinically, many features in common. I refer to yellow fever and dengue. (1) Their respective germs exist in the blood and are ultramicroscopic; (2) their germs are conveyed to man by the same species of mosquito, *Stegomyia calopus*; (3) one attack confers absolute or relative immunity; (4) in both there is a primary fever and generally a secondary fever; (5) in both there is marked flushing of the skin, violent headache, general aching, and a rapidly attained high temperature which is generally associated with a relatively slow pulse; the duration of the primary fever—three, four, or five days—is about the same in both. These etiological and clinical features held in common suggest some kind of relationship as regards the respective germs. Carlos Finlay of Havana was the first to endeavour to prove experimentally that yellow fever was conveyed by mosquito bite, and he distinctly indicated *Stegomyia calopus* as the species concerned. His experiments were neither numerous nor convincing, and the subject was dropped till the American commissioners—Reed, Carroll, Agramonte, and Lazear—took the matter up and definitely established the fact that yellow fever is transmitted by the bite of *Stegomyia calopus* and, in nature, by no other means. The practical application of this discovery, in Havana and on the Panama Canal by Gorgas and his colleagues, and by others elsewhere in tropical America, has led to what must be regarded as one of the greatest triumphs of preventive medicine, whether in the tropics or elsewhere. Any claim for a share in this important achievement that might be advanced for British workers can be at most only an indirect one.

Fortunately the deadly yellow fever has hitherto been confined to tropical America and West Africa, extending to Western Europe and parts of America only at long intervals and only during the hot months of the year, and even then only in circumscribed epidemics. Not so dengue; it occurs in extensive epidemics throughout the entire tropical and subtropical belts, where in certain places it is more or less endemic. Why yellow fever has not a similar distribution is hard to explain, seeing that both diseases are conveyed by the same *Stegomyia* mosquito. It is only quite recently (1916) that *Stegomyia* has been proved to be a vector of dengue. For this important piece of information we are indebted to three Australian physicians—Burton Cleland, Bradley, and McDonald. It is true that previous workers had blamed the mosquito as the vector of the germ of dengue—notably Graham in Syria in 1903, and, later, Ashburn and Craig in Manila, but in neither case were the experiments satisfactory, and it would appear now that the mosquito which they blamed—namely, *Culex fatigans*—is not the only transmitter, if it be a transmitter at all. The Australian physicians referred to, although they failed with *Culex fatigans*, succeeded in communicating dengue, under conditions which completely excluded every possible source of fallacy, by infected *Stegomyia calopus*.

PAPPATACI FEVER.

Pappataci fever—an ephemeral fever of approximately three days' duration and regarded sometimes in tropical countries as a fever of acclimatization—has long been known to tropical practitioners. Shortly before the part played as vector by *Phlebotomus papatasi* was known the clinical characters and specific nature of this fever were described and recognized by James in India and McCarrison in Chitral. Subsequently Birt confirmed the discoveries of Doerr, Franz, and Taussig as regards the part played by *Phlebotomus*, and British naturalists have worked out in a great measure the bionomics of that insect.

UNDIFFERENTIATED FEVERS OF THE TROPICS.

There can be little doubt that in addition to the foregoing there are other fevers of a specific nature peculiar to the tropics, whose germ causes and vectors have hitherto escaped detection. Many attempts have been made by British observers, particularly Crombie and Leonard Rogers, to classify these fevers on a clinical basis, but until the germs or their vectors have been recognized, any arrangement of this nature can be regarded only as a temporary one.

HELMINTHIASES.

Trematodes.

Of late years many additions have been made to the list of trematodes invading tropical mankind, as well as to our knowledge of the pathological effects and life-histories of the more important of them. For much of this we are indebted to British investigators.

I may cite the new West African fluke, *Watsonius watsoni*, discovered by Dr. Watson in 1904, and since found to be not uncommon in certain parts of Nigeria; *Gastrodiscus hominis*, discovered by Lewis and McConnell in India in 1876; *Echinostoma malayanum*, by Drs. Macaulay and Stanton in 1911 in the Malay States; *Clonorchis sinensis*, by McConnell, in 1874; *Opisthorchis novercæ*, by Lewis and Cunningham, in 1872; *Fasciolopsis buskii*, by Busk, in 1843; *Paragonimus westermanii*, for the first time in man, by Ringer in Formosa in 1880, its ova having been recognized previously and independently by Baelz and the writer as a characteristic feature in the sputum of patients suffering from a somewhat serious form of endemic hæmoptysis occurring in Japan, Korea, Formosa, and the Philippines.

Schistosomiasis.

These discoveries, though interesting to the helminthologist, are of comparatively small importance to the pathologist, especially if compared with the most recent discoveries in connexion with that peculiar family of trematodes, the Schistosomidae, including *Schistosoma hæmatobium* (Bilharzia), *Schistosoma mansoni*, and *Schistosoma japonicum*.

Since Bilharz, in Egypt, in 1851, discovered the parasite which bears his name it has been ascertained that this trematode is widely distributed throughout the African

continent, the adjacent islands, and in parts of Asia; that in many districts it is very prevalent—for example, Lower Egypt, where it affects one-third and in some places even 90 per cent. of the fellaheen population; that it is the cause of grave and even fatal disease; and that it has a decidedly deteriorating influence on the general health and therefore on the economic condition of the seriously affected area. Its pathological effect has been fairly exhaustively studied of late years, especially by Madden, Milton, Sandwith, and others, and the morphology of the adult worm and its ova determined, but the important matter of its life-history and the channels by which it enters the human body were until quite recently (1916) either quite unknown or at most mere matters of speculation. Dr. Leiper of the London School of Tropical Medicine, by a series of brilliant observations and successful experiments, has now completely filled in this hiatus in our knowledge, and has thereby placed in the hands of the sanitarians a sure guide in developing methods for the prevention of a disease which hitherto has proved the despair of the therapist. The history of Leiper's discoveries is interesting, not only as regards the subject they concern more particularly, but also as once more showing how what at the time appears to be a discovery with relatively small bearings may, sooner or later, lead to others of vastly greater importance.

A chronic and very fatal disease characterized by enlargement of the liver and spleen, blood and slime in the stools, anaemia, and ultimately ascites, had been recognized for a considerable time as endemic in certain parts of Japan and China. Subsequently the ova of a trematode were found to be a feature in the stools and organs of such cases. Still more recently Katsurada found in the liver of cats from one of the endemic areas numerous schistosomes containing eggs identical to all appearances with those found in the faeces of the human subjects of this disease; and still later, 1905, Catto found the same parasite and eggs in the organs of a Chinaman who died in Singapore. The disease is now known as Katayama's disease. Japanese observers have found that its parasite, *Schistosoma japonicum*, can be communicated to cats simply by immersing them in the water of certain rice fields in the endemic area. It was not essential that the water should be swallowed; simple immersion of part of the body of the cat sufficed. Myari succeeded in infecting animals from a mollusc common in these rice fields. He traced the development of the trematode in the mollusc and concluded that man acquired infection by working in the rice field, a conclusion supported by the experience of Europeans in China, principally sportsmen devoted to snipe shooting, who, it is to be presumed, had acquired the disease in wading through rice fields or swamps. Leiper, impressed by these observations and recognizing their possible bearing on bilharzia disease of Egypt, applied for and obtained permission and facilities from the London School of Tropical Medicine to proceed to the Far East to familiarize himself with and to test Myari's conclusions. The latter, somewhat modified, he confirmed. Returning to England, he placed the matter before the War Office authorities, who, recognizing the importance of bilharzia disease to the large body of troops assembled in Egypt, and acting in concert with the Medical Research Committee, commissioned Leiper to proceed at once to that country to study locally the etiology of bilharziasis and to suggest measures for its prevention and for the protection of the troops. In a very short time Leiper, assisted by Drs. J. G. Thomson and Cockin, ascertained that on emerging from the terminal-spined egg, opportunity serving, the miracidium of *Schistosoma hæmatobium* enters the liver of a fresh-water mollusc, a species of *Bullinus* (*dybowskii*), very common in the irrigation canals of Egypt, and transforms into a sporocyst and daughter sporocysts, wherein vast numbers of cercariae develop. The cercariae ultimately escape into the water, penetrate—opportunity offering—the skin of man or other vertebrate, and, dropping their tails in the passage, find their way into the liver of the vertebrate host, wherein, after six to ten weeks, they attain sexual maturity, becoming adult trematodes, which, passing into the veins of the bladder, produce the characteristic terminal-spined eggs which escape in the urine.

During these investigations Leiper was able to settle another and much disputed point in connexion with bilharziasis. It had long been recognized that there are

two types of bilharzia ova, one terminal-spined and passed principally in the urine and only occasionally in the faeces; the other lateral-spined and, practically, found exclusively in the faeces. Both types of ovum were generally attributed to the same species of trematode, the difference in the position of the spine being variously explained. In 1903 the writer, in examining the faeces of an Englishman from the West Indies, encountered numerous lateral-spined ova. Seeing that the patient had never visited Africa or any other region where bilharziasis was known to be endemic, that the urine contained no terminal-spined ova, and that, although thousands of examinations of the urine must have been made in the West Indies, bilharzia ova had never been reported from that part of the world, he suggested that the schistosoma producing these lateral-spined ova must belong to a species other than that producing terminal-spined ova. Sambon, adding many additional reasons, concurred in this view and paid me the compliment of naming the new species *Schistosoma mansoni*. Looss, who considered that this trematode did not require an intermediary, refused to accept the species. Leiper, however, in the course of the investigations just referred to, found that the miracidium of the lateral-spined ova enters a species of snail, *Planorbis boissyi*, quite distinct from the *Bullinus* favoured by the terminal-spined ova, and that on reaching the vertebrate host developed into a sexually mature schistosoma anatomically quite distinct from that resulting from infection from the miracidium of the terminal-spined ovum. Thus *Schistosoma haematobium* produces only the terminal-spined ova, and *Schistosoma mansoni* only lateral-spined ova, and are distinct species. Quite recently many cases of lateral-spined bilharziasis have been reported from the West Indies and Brazil, but never a case of terminal-spined bilharziasis, so that now there can be no question as to the validity of the new species *Schistosoma mansoni*. In further confirmation of this conclusion Lutz has found that a *Planorbis* is its intermediary host also in Brazil.

Dracontiasis.

Although the anatomical features of the adult guinea-worm and of its larva had been ascertained, little was known of the life-history of this formidable parasite until Fedschenko discovered in 1870—a discovery subsequently confirmed by the writer—that the larva on being passed into water enters the body of a fresh-water cyclops, wherein it undergoes extensive developmental changes. In 1907 Leiper was sent by the London School of Tropical Medicine to West Africa to endeavour to ascertain in what way the parasite after leaving cyclops returns to man. He found that if the infected crustacean were immersed in a weak (0.22 per cent.) solution of hydrochloric acid (in imitation of gastric juice) the cyclops was immediately killed, whilst the included parasites, on the contrary, were stimulated to great activity, and bored their way through the integument of the cyclops. This experiment, he conjectured, indicated the route likely to be followed by the guinea-worm in nature. As confirmatory experiment on man was out of the question, Leiper administered infected cyclops to a monkey, and had the satisfaction, on the death of the monkey several months later in England, of finding three female and two male guinea-worms in an advanced state of development in its tissues. From this we may conclude that the infection is acquired by man from cyclops-infested drinking water fouled by guinea-worm carriers. Efficient preventive measures are clearly indicated by this new knowledge.

Ascaris lumbricoides.

It has been generally accepted that the experiments of Davaine, Grassi, and other Continental workers had proved that the larvae in the ripe eggs of ascaris were hatched out in the human intestinal canal, and therein immediately proceeded to sexual maturity. Quite recently, however, the experimental work of Stewart tends to show that the life-history of this very common parasite may be not quite so simple. Sambon already had pointed out that the papilla or beak, a conspicuous feature in the larval ascaris, indicated that the little organism at an early stage of its existence bores its way into the tissues. Stewart has now shown that if ripe ascaris eggs are fed to a mouse many of the larvae liberated in the intestinal canal pass to the lungs, and, if the dose of eggs is large, may even induce fatal pneumonia. The complete bearing

as regards man—the normal host of *Ascaris lumbricoides*—of this observation is not quite apparent, but it certainly goes a long way to prove Sambon's view that, before attaining sexual maturity, the parasite must enter the tissues of its human host.

Filariasis.

In 1872 Timothy Lewis, in India, ascertained that the larval filaria discovered by Demarquay and Wucherer in pathological fluids was normally a parasite of the circulation. He called it *Filaria sanguinis hominis*. In 1876 Bancroft, in Australia, discovered the parental worm, *Filaria bancrofti*. Subsequently, in 1878, the writer ascertained that a *Culex* mosquito served as its intermediary host, abstracting the microfilaria from the blood and providing it with an opportunity for undergoing important developmental changes, during which it increases in size from a microscopic object to one just visible to the naked eye, and possessing an alimentary canal as well as remarkable powers of locomotion. In 1900 Low at the London School of Tropical Medicine, and subsequently James in India, made the important discovery that at this stage of development the larval worm passes into the labium of the mosquito's proboscis, and gets back into man direct, the old idea of the mosquito dying on the water and the embryos escaping into this medium and so reaching man, being thereby, if not absolutely disproved, rendered improbable. Noè, Grassi, and Fülleborn in the case of the allied parasite (*Filaria immitis*) of the dog, and Bahr in the case of the human parasite, have shown the exact mechanism of how this takes place. Finally, the metamorphosed embryos arrive at the lymphatics, where development is completed and the new generation of embryo filariae born.

When working in China at the life-history of the filaria I stumbled on the phenomenon known as "filarial periodicity." The microfilariae, I found, under normal circumstances come into the general circulation in the evening, increase in number till midnight, and gradually disappear towards morning, being almost entirely absent from the peripheral circulation during the day, when, as I subsequently ascertained, they lie up in the lungs and greater blood vessels. Stephen Mackenzie showed that by inverting the habits of the human host as regards the times of sleep this periodicity was correspondingly inverted, the filariae then coming into the peripheral circulation during the day and disappearing from it at night. For many years it was believed that this type of periodicity was observed by *Filaria bancrofti* embryos in all countries and climates. It certainly applies in most instances to China, India, Africa, and America, but we now know that it does not hold good for the islands of the Pacific—lands in which filariasis is particularly prevalent. Thorpe was the first to notice this, and later Lynch and others, especially Bahr, confirmed his observation in Fiji and elsewhere.

A larval filaria described by Ashburn and Craig in the Philippines in 1906 under the name of *Filaria philippinensis* has recently been proved to be only an example of *F. bancrofti*, adults from such cases being indistinguishable from the latter. Further, Leiper, after careful study, has failed to find any anatomical differences between the adult worms from Fiji and those from Asia and elsewhere. It seems to the writer that Bahr may have supplied the explanation of the discrepancy as regards periodicity between the ordinary and the Pacific microfilaria. This observer has shown that although in Fiji, as elsewhere, the night-feeding *Culex fatigans* is an efficient intermediary for the filaria, it is not the usual or most efficient intermediary in that group of islands. In Fiji the day-feeding mosquito, *Stegomyia pseudo-scutellaris*, is not only a very common insect but in respect of efficiency as an intermediary for the filaria is ahead of *Culex fatigans*, and he concludes that the filaria has partially adapted its habits to those of its favourite intermediary in the Pacific, just as it has adapted itself to the habits of *Culex fatigans* and other nocturnal mosquitoes, its favourite intermediaries in Asia, Africa, and America. It may be suggested that the explanation might lie in some peculiarity of climate or other circumstance peculiar to Fiji and the Pacific islands generally; but the same writer has shown that the microfilaria of coolies imported from India, who, presumably, had brought their parasites with them from their native country, retained the

nocturnal periodicity habit even after years of residence in Fiji, whilst Indians born in Fiji acquired the non-periodic filaria only. The point, however, is not settled, as *Culex fatigans* does exist and can carry the filaria in Fiji.

Although in many instances the filaria appears to be non-pathogenic, nevertheless, seeing that it is apt in a considerable proportion of instances to give rise to serious disease, especially elephantiasis, and that it occurs in a large proportion (5 to 75 per cent.) of the inhabitants of many tropical countries, it is a very important element in tropical pathology.

Many British workers have studied the pathological bearings of this parasite, and have definitely linked it up as the cause of lymphangitis, of chyluria, varicose groin and axillary glands, lymph scrotum, chylocele, various forms of lymphangiectasis and of tropical elephantiasis, and also of fatal septicaemia supervening on suppuration in abdominal and other seats of lymphatic varix. Of interest are the observations of Wise in Demarara, and Bahr in Fiji, on the cretified remains of effete filariae in the lymphatic glands and elsewhere.

Other Microfilariae.

As opportunity presented itself the writer made systematic examination of the blood of the natives of many different tropical countries, and in this way was enabled to discover the blood-haunting larval filariae of three additional and specifically distinct nematodes, namely, *Filaria loa*, *Filaria perstans*, and *Filaria demarquayi*.

The embryos of *Filaria (loa)*, the eye worm of tropical West Africa and its hinterland, and the cause of the peculiar condition known as "Calabar swellings," so common in Europeans in those regions, and so often mistaken for erythema nodosum, resemble very closely those of *Filaria bancrofti*. It differs, however, from the latter in minute anatomical details, and also in observing an exactly opposite periodicity, entering the general circulation during the day and disappearing from it at night. This circumstance led the writer to suggest that its liberating and intermediary host must be a biting fly of corresponding habit, and as the mangrove fly, *Chrysops dimidiata*, was very common and very active during the day in the endemic districts, he suggested that it might be the intermediary host, and therefore responsible for the spread of the parasite. This suggestion has been proved to be correct by Leiper, whose observations have been confirmed quite recently by Kleine in the Cameroons.

Acanthocheilonema perstans.

The larval form of this parasite was found in 1891 in the blood of a Congo negro suffering from sleeping sickness, and subsequently found in many cases of that disease. I concluded that it might be the cause of this condition, but Low and others have shown that this is not so. We now know that it is a very common parasite in West Africa, on the Congo, in Uganda, in British Guiana, and probably elsewhere in the tropics. Daniels was the first to find the adult worm in aboriginal Indians of British Guiana.

Filaria demarquayi.

The larvae of this species I found in the blood of the Caribs of St. Vincent, West Indies, and subsequently in aboriginals of British Guiana and possibly of New Guinea. Low has shown that it occurs also in others of the West Indian Islands—Dominica, Trinidad, and St. Kitts. He experimented with many insects to determine the intermediate host, but failed to find it. The adult form was discovered and described by Daniels in 1898. Whether the two last-mentioned nematodes produce any serious pathological effects has not been absolutely determined. It is unlikely that they do so.

SPRUE.

Sprue is one of the more important diseases of the tropics, particularly as regards Europeans, among whom, especially among the older residents, it is a very common, very intractable, and very deadly disease. It is only of late years that its characters, symptoms, and diagnosis have come to be generally recognized, mainly through the writings of Fayrer, Thin, myself, Carnegie Brown, Begg, Castellani, and Bahr. The histopathology of the disease has been well worked out by British pathologists. There has been much speculation about the assumed specific cause—bacteria, hyphomycetes, and even helminths having

been at different times incriminated; so far nothing definite in this respect has been arrived at. We are therefore still at a loss to indicate a scientific prophylaxis of a disease which amounts to a positive curse in such places as Ceylon, the Malay States, parts of India, of China, and of many other tropical countries.

THE DYSENTERIES.

It is only of late years that anything approaching to a scientific conception has been attained of what is indicated by the term "dysentery." Formerly the word was taken to indicate one definite and distinct disease, but nowadays we must regard it as indicating several forms of colitis brought about by a number of specifically distinct disease germs. Thus we have protozoal dysenteries attributable to such germs as the *Entamoeba histolytica*, the malarial parasite, leishmania, and *Balantidium coli*; helminthic dysenteries resulting from invasion of the walls of the colon by *Schistosoma japonicum* and *Schistosoma mansoni*; bacterial dysenteries produced by the several members of the *Bacillus dysenteriae* group, and probably of other bacteria. Although most of the original discoveries which have enabled us to arrive at this classification of the dysenteries are to be attributed to workers other than British, some of them may be fairly assigned to our fellow-countrymen, especially those having a bearing on the prevention of these diseases, such as the elucidation of the part played by dysentery carriers and their treatment.

BERI-BERI.

How many etiologically distinct forms of tropical multiple peripheral neuritis are included under the term "beri-beri" it is at present difficult to say; probably there are several. If we confine the term to that form of endemic multiple peripheral neuritis occurring in the Malay archipelago, China, and Japan, evidence is rapidly accumulating that, if it be not the only and sole cause of the disease, a dietary deficient in the vitamins essential for healthy nutrition has much to do with it. Although the initial observations which have led to this conclusion are to be credited to a Dutch physician—Eijkman—much has been done by British workers in narrowing the field for observation and in giving precision to conclusions. The observations of Eijkman on beri-beri in the Dutch East Indies distinctly indicated that in some way or other the disease was associated with a particular kind of prepared rice. Later Braddon insisted on this; and although his explanation of the *modus operandi* of the rice factor was not the right one, yet his insistence led to careful and fruitful investigation and experiment by Fraser and Stanton under Government auspices. The last named observers have distinctly shown that a leading element, if not the only element, in the causation of beri-beri, at all events in the Malay States, is absence (owing to excessive milling) of the pericarp and germ of the rice which constitutes the staple food of the Chinese, Indian, and Japanese coolie. And, further, they have shown that the administration of the millings of the decorticated and highly polished rice can arrest the development of a threatened attack of beri-beri, and, if it is not too far advanced, cure the disease. These observations on man are supported by experiment on the lower animals, especially on fowls, in which, as Eijkman and many others have shown, a diet exclusively of the incriminated forms of rice induces a polyneuritis closely resembling, if not identical with, that of beri-beri. The conclusions of Fraser and Stanton have been substantiated by many independent observers in the Philippines, in Japan, and elsewhere, and action based on these conclusions has had most happy results in prisons, asylums, hospitals, and other public institutions, as well as on native labour in plantation and mining camps. Mott, Halliburton, Durham, and Hamilton Wright have made important contributions to the pathology and anatomy of this disease.

SKIN DISEASES.

Mycetoma.—Since Vandyke Carter, in 1859, demonstrated the mycotic nature of the melanoid and ochroid forms of what is variously termed Madura foot, fungus disease of India, and mycetoma, considerable attention has been given to this and allied diseases by British and French pathologists, notably in Britain by H. J. Carter, Kanthack, Boyce, Hewlett, Adami, Kirkpatrick, and many others. Owing to the labour of these observers, it is now known

that mycetoma occurs in many tropical countries besides India, and in a variety of forms, and that the germs are introduced through wounds in the skin.

Ulcerating granuloma of the pudenda was first described in India by McLeod, and in 1896 by Conyers and Daniels in British Guiana, and subsequently by other British workers in Africa, Australia, and elsewhere. Donovan called attention to certain coccoid parasites included singly, or more usually in groups, in the large mononuclear cells obtained by scraping the surface of the characteristic ulcers. Intravenous injections of antimony have lately been used with good effect in the treatment of this disease by workers in Brazil, and Low and Newham have recently published the details of a case in England cured by this method.

The systematic study of the tropical dermatomycoses had been neglected until recent years, and until the adoption of Sabouraud's methods by Castellani and Chalmers had brought about a certain amount of order into this little understood department of tropical dermatology. Other British workers have from time to time contributed to the advancement of the subject, and I may mention Turner and Sir William MacGregor. The tropical practitioner is no longer satisfied with a comprehensive diagnosis of the mycotic skin diseases by the expression "dhotie itch." He now recognizes that there is a great variety of hyphomycetic skin disease both in the native and in Europeans; he distinguishes between erythrasma, tinea cruris, tinea imbricata, pityriasis versicolor, and so forth, and he knows now that these are only a few of the many forms of hyphomycetic skin disease fostered by the heat and moisture of tropical climates and contact with tropical animals.

Vomiting Sickness of Jamaica.—For many years it has been known that a peculiar disease, called "vomiting sickness," occurs from time to time in certain districts in the island of Jamaica. It is an extremely fatal disease, the mortality being anything from 80 to 90 per cent. It occurs particularly in children, although sucklings are exempt. Naturally its etiology has been the subject of much speculation and several commissions have attempted to clear this up. Some have regarded it as a manifestation of yellow fever, others of malaria, but it has been reserved to Dr. H. Harold Scott, Government bacteriologist, Jamaica, to solve the mystery. He has found that the so-called disease is produced by poison liberated in some mysterious way in immature or damaged ackees, the fruit of *Blighia sapida* (a tree very common in Jamaica) and much used by the negroes of that island. Shortly after the consumption of damaged fruit, especially of the soup prepared from the damaged fruit, vomiting sets in; presently this subsides, to be followed three or four hours later by a recurrence and a rapid supervention of convulsions, coma, and death. The average duration of the illness is little over twelve hours. Dr. Scott has proved that certain animals are susceptible to the poison and show *post mortem* a remarkable fatty degeneration of the liver and other tissues, a condition which is also a notable feature in fatal cases of vomiting sickness in man.

TREATMENT OF TROPICAL DISEASES.

Many recent advances in our knowledge of the germ causes of tropical diseases and in our diagnostic methods have led to a more accurate application of certain drugs long recognized as efficacious in particular types of dysentery, and to the introduction of new drugs and methods of treatment in other diseases. I can allude to a few only of these drugs, and such as are justly attributable to British workers. The value of atoxyl in the treatment of trypanosomiasis was first indicated by Thomas, then of the Liverpool School of Tropical Medicine, and the use of salts of antimony in the same disease by Plimmer and Thomson of the Lister Institute.

Sir Leonard Rogers, following up Vedder's work on emetine, introduced this drug to be given hypodermically as a substitute for ipecacuanha in the treatment of amoebic dysentery and amoebic hepatitis. It has recently been demonstrated that this method does not, in many instances, sterilize the individual of his amoebae, and that many of these cases become chronic carriers. Quite recently, Dale, Low, and Dobell have used a new compound, emetine bismuth iodide, by the mouth in such cases, and have found its sterilizing effect on the amoebae to be much greater than that of emetine given by hypo-

dermic injection. It is quite likely, therefore, that the oral administration will supplant the hypodermic method in the treatment of the disease in the future. Donovan and other British physicians have proposed radiotherapy in the treatment of granuloma of the pudenda, and many British practitioners in Africa and the West Indies have demonstrated the value of the intravenous injection of salvarsan and other arsenicals in tick fever and yaws.

INDIA AND MEDICAL PROGRESS.

BY

R. McCARRISON, M.D., D.Sc., F.R.C.P.,

MAJOR I.M.S.,

LAUREATE ACADEMY OF MEDICINE, PARIS.

To what extent has India contributed to the advancement of medical science?

In providing an answer to this question it is necessary to indicate that Western medicine, even at the present day, is represented in India by only about 1,000 British medical men, the major part of whom form the Indian Medical Service. One thousand British doctors in a land of over 300 million people! In a land where plague, pestilence, and famine are the crude problems of everyday life. In a land where tropical heat and torrential rains sap the vitality of the strongest frame and the resolve of the strongest will. In a land where strange diseases lurk in unsuspected places and death comes in a moment to even the most watchful.

To the teeming millions of such a land this small service has, since the earliest days of the East India Company, brought the benefits of Western medical science, carried into its waste places and most desolate outposts the standard of medical progress, and evolved sanitary order out of pestilential chaos. It has established medical schools and training colleges, and has brought into being an army of Indian-born and Indian-taught medical men. It has provided the professorial staff for the medical colleges, and has taught as well as practised the science and art of medicine and surgery. It has instituted a sanitary service, and has laid the foundations on which the science of tropical sanitation is built. It has established hospitals and dispensaries in every city and town in every district from Ceylon to the Pamirs, and has made it possible for twenty-eight and a half millions of India's people to receive the benefits of Western medical and surgical treatment in a single year. It has organized medical research and established research institutions where problems peculiar to India are studied by competent experts recruited from its own ranks. It has founded Pasteur Institutes for the treatment of rabies and the manufacture on a large scale of prophylactic vaccines and serums. It has ministered to the needs of India's army in peace, and tended to the sick and wounded in her frequent campaigns. It has organized the jail system of India, and taught her convicts trades. It has established tropical schools of medicine in Calcutta and Bombay, which bid fair to hold premier rank amongst such institutions in the world. All this the Indian Medical Service has done in the ordinary discharge of its duty, and what more?

Our knowledge of the natural sciences—botany, zoology, and geology—has been enriched by its aid. It has sifted from amongst the mass of tropical fevers a number of definite disease entities, described their etiology and symptomatology, and elucidated their cause or their mode of spread. It has made important contributions to our knowledge of other diseases of more universal distribution, discovered the means of cure of some of the tropics' most deadly maladies; and, finally, it has made striking additions to forensic medicine and to the art of surgery. It is with these, since they represent additions to the sum total of medical knowledge, that it is necessary to deal, emphasizing the fact, however, that they have been made during the performance of a task which in itself was colossal.

Let us consider, then, these contributions of India to the medical knowledge of the world.

Malaria.

The discovery by Ross that the plasmodium of malaria is conveyed to man by anopheline mosquitos (Fig. 1) ranks

FIG. 1.—*Anopheles maculipennis*, a carrier of malarial fever in Europe.

FIG. 2.—*Culex fatigans*, the chief carrier of elephantiasis.

These figures are reproduced by permission from *Mosquitos and Their Relation to Disease* (British Museum—Natural History Series, No. 4), price 1d.

not only as the greatest of India's medical triumphs, but as one of the greatest discoveries of modern times. As a result of this discovery it is now possible to control the spread of this disease, whereby an inestimable benefit has been conferred upon mankind. Through it a great light was shed upon the mode of spread by suctorial insects of other protozoal diseases, by which light the problems of the propagation of dengue, yellow fever, sleeping sickness, and other diseases of the tropics have reached, or are gradually reaching, solution. Truly Ross's achievement was epoch-making, and laid the foundation on which the science of tropical hygiene is built. By its aid some of the earth's most pestilent places have been made habitable. Witness its triumphs in the Panama Canal zone, in India, in East and West Africa, and in Greece, Italy, and Egypt—triumphs which Ross's discovery alone made possible.

Ross, whose services to humanity have received the highest recognition of almost every country in the world, including the award of the Nobel Prize, has been followed in India by others whose researches have brought to light the important truth that different species of anopheles are responsible for the spread of malaria in different localities, as, for example, *Noccellia stephensi* in Bombay and *Pseudomyzomyia ludlowi* in the Andaman Islands. Accurate studies of the habits and breeding places of different species of anopheles have enabled tropical sanitarians to conserve their energies to the destruction of the responsible mosquito in each locality.

In the treatment of this disease by quinine the pioneer work of Edward Hare, and in more recent years of MacGillchrist, must not be forgotten—the former, by introducing, in 1847, the practice of giving quinine without waiting for remission, was instrumental in saving many lives and in putting to an end the pernicious, and then universal, system of bleeding in this disease; the latter, by his careful researches on the value of different products of quinine, has added greatly to our knowledge of its treatment and to the treatment of blackwater fever.

Kala-azar.

To the patient researches of Donovan, of the Indian Medical Service, the world owes the discovery of the causal agent of this malady, and the recognition of *Leishmania* as disease-producing agencies. More recently Patton and Mackie, of the same service, have brought forward experimental and other evidence which goes far towards elucidating many of the complex problems connected with its spread. Younger members of the service have also added greatly to our knowledge of the epidemiology of this deadly malady.

Other Tropical Fevers.

It was Vandyke Carter who in India worked out the origin and development of the disease known as famine

fever, relapsing fever, or spirillum fever; and Mackie who, in more recent years, discovered that *Pediculus vestimentorum* was its carrier.

To this service is also due the credit of having separated three-day fever of Chitral—now known as sandfly fever—and seven-day fever of Calcutta, from amongst the mass of the unclassified fevers of the tropics, and of indicating the sandfly as the probable source of spread of the former malady, an indication which later researches in other countries proved to be fully justified.

Plague.

It is to India that the world owes its knowledge of the rôle played by the rat and by the rat-flea (Fig. 4) in the propagation and spread of bubonic plague—discoveries which were placed upon the statute book of medical progress by Liston and Bannerman of the Indian Service and by the Indian Plague Commission. As a result of these

FIG. 4.—The rat-flea (*Xenopsylla cheopis*), a carrier of plague.

discoveries, it has been possible to prevent the spread of plague in countries whence it has been carried in ships and merchandise from India. Furthermore, protection is afforded to the individual in plague-stricken countries by the method of prophylactic inoculation with killed cultures of the bacillus—a method which was introduced at Bombay in the year 1897 by Haffkine of the Indian Service.

Cholera.

It is to India that the world owes a great part of its knowledge of cholera, and the whole of its knowledge of the treatment and mode of spread of this deadly malady. Leonard Rogers, amongst his other monumental contributions to tropical medicine, has, by his hypertonic saline treatment of cholera, robbed it of half its terrors, and reduced its mortality from 70 to 23 per cent. Greig, by demonstrating the cholera vibrio in the lungs, the liver, and other tissues, as well as in the urine, has within the last few years provided a wealth of information

in regard to the human factor in its dissemination. He has shown that cholera can no longer be regarded as solely water-borne, and that the human subject is the reservoir and the carrier of its infective agent (Fig. 5).

To India also belongs the honour of having perfected, through Haffkine, as early as 1893, a method of anti-choleraic inoculation the protective value of which has proved of the highest value.

Dysenteries.

For the major part of its knowledge of the treatment of the dysenteries the medical profession of all lands is indebted to India. Buchanan's introduction of the saline treatment of bacillary dysentery provided a weapon of wonderful effect against this form of the disease; and even now that serum-therapy affords a specific means of cure the saline treatment remains such a reliable addition to our armamentarium as can ill afford to be dispensed with.

Few discoveries in the field of therapeutics have been of such signal service to mankind as that of the specific action of emetine hydrochloride when administered hypodermically in amoebic dysentery—a discovery for which we are indebted to Leonard Rogers of the Indian Medical Service. The simplicity of this method of treatment and the certainty of its action when properly administered has reduced the mortality of this disease to an enormous extent. It has provided an effective prophylactic measure against the occurrence of those dangerous complications of amoebic infections of the bowel, *hepatitis* and *liver abscess*, and an efficient means of their cure, while it has greatly reduced the necessity for operation in amoebic infection of the liver, simplified our operative procedures, and reduced their risk.

Rabies.

India also, through its British medical men, has added greatly to our knowledge of the Pasteur treatment of rabies, and has improved upon that of Pasteur himself. In one of India's Pasteur Institutes alone as many cases are treated in a single year by these improved methods as in the whole of the rest of the world put together.

Leprosy.

India has within recent years made notable advances in the treatment of her lepers—advances which hold out the confident hope of the early evolution of a means of cure of this unclean and fatal malady. (Figs. 6 and 7.)

Goitre and Cretinism.

In the elucidation of the mystery which from the time of Hippocrates has surrounded the origin of these diseases of the thyroid and parathyroid glands, India has, within the last ten years, been able to play a notable part. Research has shown that intestinal organisms are the agencies mainly responsible for their production. (Figs. 8, 9, 10, and 11.)

The Natural Sciences.

In the field of botanical research the work of Hill and Prain, to mention only two of India's botanists, has added greatly to our knowledge of the flora of the tropics, while Bose, an Indian-born subject, has gained for himself a pre-eminent place in connexion with his studies of plant physiology.

In the domain of zoology the Indian Medical Service has provided such authorities as Day, Alcock, and Wall, who have greatly enriched our knowledge by the study of deep sea fauna and of reptilia, to mention but two fields of their activities. Modern Indian investigators also have done much to classify and describe many new species of malaria-bearing and other mosquitoes; while such geologists as Falconer and MacClelland have rendered the greatest services in contributing to our knowledge of the earth's crust.

Hypnotism.

And let it not be forgotten that even before British medical science had given to the world the incalculable blessing of anaesthesia James Esdaile, of the Indian Medical Service, had demonstrated the miraculous utility of mesmeric anaesthesia, under which he performed painlessly hundreds of operations of great gravity. The use of ether and chloroform has overshadowed Esdaile's brilliant discoveries, but these will find their place again in the armamentarium of the scientific physician and surgeon of the future, and their application in the relief of human suffering will go far to extract from the chaff of Christian Science and faith healing the full ears of wheat which lie buried in them.

Surgery.

Finally, in general surgery the members of the Indian Medical Service and their pupils have conferred such benefits on the people of India as to leave one awestruck at the magnitude of their operative work. No less than 1,050,000 of India's people received the benefits of surgical treatment in a single year. India's surgeons have never departed from the teachings of the father of all modern surgery—Lord Lister; they have continued to recognize the value and the place of antiseptic, as opposed to aseptic methods, in the treatment of surgical conditions in the

tropics, where wounds are so subject to soil infection. To them the surgical lessons of the present war have come as no surprise, while they have long recognized and practised the prophylactic use of antitetanic serum in such conditions as compound fractures and other infected wounds. So much so is this the case that deaths from tetanus in Indian hospitals, which were formerly frequent, have been reduced to a minimum.

But there are three departments of surgical practice in which Indian surgeons have led the world, and in which their supremacy is indisputable—litholapaxy, ophthalmology, and rhinoplasty. With the perfection of

Fig. 5.—Section of wall of urinary bladder showing the cholera vibrio in the submucosa. The round cells infiltrating the submucosa are also shown. (Greig.)

Fig. 6.

Fig. 7.

the first for the cure of vesical calculus, the names of Keegan and Freyer must be associated for all time. This procedure has led to the abandonment of the practice of cutting for stone, and has added to the art of surgery a method of treatment of the highest value.

The methods of ophthalmological practice, especially in regard to the treatment of cataract and glaucoma, which the world owes to such men as Maynard, Herbert, Elliot and Smith, have brought to India's shores students from all lands, and conferred inestimable benefits upon mankind.

Plastic surgery of the face also owes much to the unrivalled experience of Indian surgeons, and the methods of technique evolved by them are now largely employed by modern military surgeons in the present war. Keegan's writings on rhinoplasty are amongst the most important contributions to this subject to be found in the literature of modern surgery.

The Present War.

And in this conflict of nations, to what extent have India's contributions to medical science aided in lessening its terrors and alleviating its pains? Witness the ravages of bacillary and amoebic dysentery in the armies of all belligerents, and the blessings which the Indian treatment by salines and by emetine have proved themselves to be. It is not too much to say that thousands of lives have been saved by these means. It is to the emetine treatment of amoebic dysentery also that the rarity of its dreaded sequel—liver

inoculation is a striking example of the far-reaching effect of scientific methods which had their origin in India. Witness also the important part which their knowledge of the human factor in the spread of cholera has enabled Indian medical officers to play in the prevention of

outbreaks of cholera in Mesopotamia, and in the cutting short of others amongst those who had not received the benefits of protective inoculation. And witness the great reduction in the usual high rates of mortality of cholera amongst those who developed the disease which Rogers's hypertonic saline treatment alone made possible. Relapsing fever, also, which made its appearance amongst the troops in the Eastern Mediterranean, was early exterminated owing to our knowledge of its mode of spread by the body louse—a knowledge which India has been instrumental in providing. And, in a lesser degree, it has been possible to afford the troops protection against sandfly fever, which, although a non-fatal malady, is capable of materially reducing the numbers of effectives

in a susceptible community and of predisposing to maladies of greater gravity.

These are amongst the benefits which India may proudly claim to have made available for friends and foes alike in the present war. Truly her medical service has triumphantly borne into the pestilential places of the earth the standard of medical progress, and has emblazoned on its folds such victories over disease as no other

FIG. 8.—Experimentally produced congenital goitre in kid (McCarrison).

abscess—is to be attributed. Witness also the check which protective inoculation by vaccines has placed upon the spread of plague and of cholera in Gallipoli—a method of protection which was inaugurated in India. The results achieved by this means are all the more remarkable when it is remembered that plague and cholera were prevalent amongst the Turks in the near neighbourhood of the allied troops during the Gallipoli campaign. It is due to Indian medical research to emphasize the fact that it was Haffkine's work in the years 1893-7 which preceded and inspired research on the prophylactic use of vaccines against bacterial diseases. The success which has crowned the use of antityphoid

country's medical service can boast. Malaria, tropical fevers, plague, cholera, dysentery, liver abscess—these are amongst its conquests; while across the art of general surgery and of ophthalmology the service has written its name in imperishable letters.

A NATIONAL INSTITUTE has been founded in Milan for the care and education of children suffering from mental weakness, anomalies of speech, disorders of hearing, and nervous troubles. Attached to the institute are a psychopaedagogic laboratory under Professor Agostino Gemelli, an ear department under Dr. Ugo Ambrosini, and sections of "orthophreny" and "orthophony" under the direction of Professors P. Parisé and A. Hecker.

THE TREATMENT OF SCABIES BY CHLORINE GAS.

BY

G. HERBERT CLARK, TEMP. CAPTAIN R.A.M.C.,

AND

H. S. RAPER, TEMP. CAPTAIN R.A.M.C.

WHILST one of us was carrying out the training of troops in the use of anti-gas measures involving exposure of the men to chlorine gas, the officer commanding one of the battalions made the remark that, "If the gas had done nothing else, it had cleared the camp of scabies." Subsequent interrogations of the medical officer confirmed the observation to a great extent.

Scabies being a parasitic disease, it did not seem unreasonable to suppose that the "gassing" to which the men had been subjected had proved fatal to the acarus. It might reasonably be expected, however, that cases of scabies in the camp would not be very severe or they would have been sent into hospital. Also other common parasitic conditions, such as pediculosis, might easily have been confused with scabies in the observations mentioned above.

At any rate, a careful investigation appeared to be worth while, in which the concentration of the gas to which the patients were exposed and the duration of the exposures were carefully controlled. Cases of indubitable scabies were therefore used in the investigation.

Through the kindness of the D.D.M.S., London District, about sixty cases of scabies in non-commissioned officers and men and fourteen cases in officers have been treated by exposure to chlorine. The details of the treatment differed in the two cases.

The non-commissioned officers and men were exposed to a concentration of one to two parts of chlorine per thousand of air (by volume), the service gas helmet being worn as a protection. The exposures were of five minutes' duration and occurred on successive days. Usually four exposures were given, but in some instances this number was exceeded.

The patients had a hot bath before their first treatment and wore ordinary hospital clothing. At the first exposure the bedding was placed in the "gassing" chamber. The officers wore a box respirator as protector, and were exposed to a concentration of between two and three parts of chlorine per thousand of air. The exposure lasted twenty minutes.

A bath was taken on the morning of the first day of treatment and not again, except in one case, until the day after the last exposure of gas. The number of exposures given and the intervals between them were varied in order to find out the best conditions of treatment.

A few of the cases were given four exposures on successive days, and then, after two days' interval, two more exposures on successive days. Others received two exposures on the first two days, then, after two days' interval, two further exposures on successive days. Three of the officers were given two exposures on the first two days, and then, after three days' interval, one more exposure only. On the first day of treatment the officers' underclothing, sleeping garments, and gloves were exposed to the gas, and clean bed linen was ordered the same night. The clothing was exposed for twenty minutes. The treatment of both officers and men was carried out in rooms with about a thousand cubic feet of air space. Chlorine was delivered into this from a cylinder, and it was found, after very little practice, that an approximation to the concentration desired could easily be obtained. The concentration in all cases was determined more exactly by drawing with a siphon a measured volume of the air through 5 per cent. sodium iodide solution, and titrating the iodine liberated with sodium thiosulphate.

If 1,100 c.cm. of air are drawn through the iodide solution, and decinormal sodium thiosulphate be used in the titration, then each cubic centimetre of thiosulphate used is equal to one volume of chlorine per 1,000 volumes of air.

The point of the delivery tube of the burette was pushed through the cork of the wash-bottle containing the sodium iodide, so that the titration could be carried out in the gas chamber. If the iodine is not over-titrated, then several determinations of the concentration can be made by refilling the siphon bottle and again drawing through the wash-bottle a known volume of air.

Results of the Treatment.

Non-commissioned Officers and Men.—Nearly sixty non-commissioned officers and men were treated under somewhat unsatisfactory conditions at a military hospital in the London district, the mode of treatment being that described above. Of the whole number, the medical officer of the hospital reported not more than 25 per cent. as cured. Many of the cases not definitely cured showed much improvement.

In view of the much more favourable results obtained in the treatment of officers, which will be referred to presently, the comparative failure of the treatment of the non-commissioned officers and men may be ascribed to the exposure to chlorine being of too short a duration, and also to the fact that the concentration of the gas used was on the average not more than one per thousand of air.

Officers.—Of the fourteen officers treated, eleven were cured and three much improved. Eleven of the officers received four or more exposures, and of these nine were cured. The two who still had apparently active lesions had received six exposures. Two officers were given four exposures on six days, the two middle days forming an interval. Both were cured; one, however, was a mild case. Three officers received three exposures only, one on each of the first two days, and the third on the sixth day. Of these, two were cured, and the third was almost free of scabies a week after the last exposure.

These figures make it appear that usually four exposures are sufficient when given on the first, second, fifth, and sixth days.

One feature of the treatment which was noted in officers, non-commissioned officers, and men was the production of a very irritable condition of the skin, especially about the scrotum and axillae, in some of the cases. It was most marked in cases which may be termed chronic, and which had been treated by sulphur in one form or another for varying periods without cure, and also more noticeable in the cases which were given more than four exposures. We have noted the same condition in ourselves whilst working in chlorine gas for various purposes. It passes away completely as a rule in the course of one or two weeks and is relieved to some extent by adding a little washing soda to the daily bath.

Details of the officers' cases are given below:

Case 1.—Severe scabies on wrists, thighs, and neck; fourteen days' history. Had been treated by sulphur baths and ointment, but made only slow progress. Was treated by chlorine gas on October 13th, 14th, and 18th, 1916. On October 18th the patient was free of scabies. Wrote a month later to say he was still free.

Case 2.—Legs and arms chiefly affected. Patient had had three months' previous treatment with sulphur in various media. He received nine treatments by chlorine gas in November, 1916—namely, on the 10th, 13th, 17th, 18th, 19th, 20th, 27th, 28th, and 29th. On the 30th he was cured.

Case 3.—Arms chiefly affected; one week's history. The disease was accompanied by dermatitis of obscure origin. Treated by chlorine gas on November 10th, 13th, 17th, 18th, 19th, and 20th, 1916. On the 23rd the condition was very much improved, but not quite cured.

Case 4.—Patient had suffered from scabies and eczema for three months, the feet, hands, arms, and back being affected. Had been treated previously with sulphur. Was treated by exposure to chlorine gas on November 14th, 16th, 20th, 21st, and 22nd, 1916. On December 1st he was free of scabies.

Case 5.—Patient's second attack during the year; one month's history. Had had no treatment. Exposed to chlorine gas on November 16th, 20th, 21st, 22nd, 23rd, 28th, and 29th, 1916; and was free of the disease on December 1st.

Case 6.—Patient's hands, arms, trunk, and legs were affected; six weeks' history. No previous treatment. Received five treatments by chlorine gas—November 16th, 18th, 20th, 21st, and 22nd, 1916—and on December 1st was cured.

Case 7.—Patient had a two months' history of scabies and furunculosis; he had undergone no special treatment for scabies. Treated by chlorine gas on November 16th, 20th, 21st, 22nd, and 23rd. Was free of the disease on December 13th.

Case 8.—Groin and thighs chiefly affected; ten days' history. Had had sulphur treatment for three days. Was treated by chlorine gas on November 18th, 1916, and three following days, and again on the 25th and 26th. Free of scabies on November 30th. Wrote from France on December 27th to say that he was still free.

Case 9.—Patient had five months' history of the disease, and had received many treatments with calcium sulphide, without effect. Treated by chlorine gas on November 20th, 21st, 22nd, 23rd, 28th, and 29th, 1916. When seen on December 14th was cured.

Case 10.—Patient had ten weeks' history of scabies. Was treated by chlorine gas on November 23rd, 24th, 25th, 29th, and 30th, 1916, and when seen on December 14th was apparently cured; later, however (December 19th), scabies had recurred.

Case 11.—A moderately severe case; three weeks' history. No previous treatment. Exposed to chlorine gas on November 25th, 26th, 29th, and 30th, 1916. Cured on December 13th.

Case 12.—A mild case, with six weeks' history. Sulphur bath treatment for two weeks. Treated by chlorine gas on November 28th and 29th, 1916, and again on December 2nd and 3rd. Cured on December 7th. Wrote on December 21st saying he was still free of disease.

Case 13.—Hands, arms, trunk, and legs affected. One week's history with rapid spread of the infection. Treated by chlorine gas on December 7th, 8th, and 12th. On December 16th the patient was free of scabies.

Case 14.—Hands, arms, trunk, and legs affected. Ten weeks' history. No previous treatment. Treated by chlorine gas in December, 1916. On December 27th there was no irritation, but apparently scabies lesions were still present.

It is only possible to surmise as to the active agent in the cure. The toxic properties of chlorine are well known, and no doubt the acarus is affected by the gas diffusing into the burrows.

It seems possible, however, that the action may be prolonged by the combination of the chlorine with the outer layer of the skin and its gradual liberation as hydrochloric acid, since it is well known that proteins form such unstable compounds. In addition to the chlorine the hydrochloric acid may thus play a part in killing the acarus or its eggs.

It is generally held that the efficacy of the sulphur bath treatment is due to the formation of sulphuric acid and by oxidation of the sulphur; and this view would be in accord with the above supposition.

The treatment is perhaps a little too difficult to carry out in civilian life without special apparatus and a "gassing" room. For army purposes, however, where respirators are supplied which protect against the concentration of chlorine used it may be valuable because it is ambulatory, no special hospital accommodation being required as in the treatment of sulphur ointment.

We should like to express our thanks to Major J. S. Morrow, R.A.M.C., of the Queen Alexandra Military Hospital, for making an independent examination of the officers, and to Drs. Shelswell and Harrison, of Holborn Military Hospital, Mitcham, for examining and reporting on the non-commissioned officers and men.

Since writing the above, our attention has been drawn to a striking instance showing the efficacy of the method for preventing the spread of scabies in a unit. Numerous cases of scabies were occurring in a mounted section which was sleeping in temporary barracks. They were all passed through a considerable concentration of gas in a state of nudity, helmets being fastened round their necks with towels. The gassing was carried out in their sleeping quarters, all their clothes and bedding being treated at the same time. The medical officer has reported that no further case of scabies occurred for more than two months thereafter.

ANAPHYLACTIC SHOCK AFTER INJECTION OF SERUM INTRAVENOUSLY.

By C. ADAM PATRICK, M.D.,
TEMPORARY CAPTAIN R.A.M.C.

THE intravenous method of injecting serum causes the patient so much less discomfort than injection into the subcutaneous tissues, and has so many other advantages, that the record of three cases in which anaphylactic shock occurred may be of interest. After a rabbit or a guinea-pig has been sensitized by an injection of serum, it is sometimes possible to kill it within a few minutes by giving it a second subcutaneous dose. In man, however, the anaphylactic symptoms which may follow a second injection of serum under the skin are rarely dangerous, and consist usually in an accelerated and exaggerated attack of serum sickness; but intravenous injection may have alarming consequences. The following are notes of three such in a series of cases of dysentery.

CASE I.

W. P., aged 24. Admitted to hospital on July 24th, 1916, with symptoms of dysentery—frequent stools of blood and mucus. Temperature 100°–102° F. *B. dysenteriae* (Shiga) was grown from faeces on the day of admission. He did not improve on the treatment he was receiving, so antidysentery serum was injected intravenously as follows: On July 30th, 25 c.cm.; on July 31st, 20 c.cm. (patient rather better); on August 1st, 20 c.cm.; on August 2nd, 20 c.cm. (patient considerably improved); on August 5th, 20 c.cm.

About one and a half minutes after the last injection the patient experienced sudden pain over the heart, went pale, and felt faint. This gave him a great fright, but he felt all right again within a few minutes. A serum rash was out all over the body by the following day. His convalescence was rapid.

CASE II.

A. D. J., aged 25. Admitted to hospital on September 15th, 1916, and died on September 17th. The patient was very ill and thin. His illness had begun on August 14th, and in the course of treatment he had received one injection of antidysentery serum on August 22nd. Diarrhoea had rather diminished before admission, but became severe again on the 16th, when the stools consisted chiefly of mucus. Bacteriological examination was negative. As he was very ill indeed on the night of the 16th, it was decided to give him intravenous saline, and the opportunity was taken to give serum along with it. The sequence of events is here tabulated:

11.20 p.m. Injection of normal saline begun.

11.25. Antidysentery serum 25 c.cm. added to saline in container after about 250 c.cm. of normal saline had been run in. The injection meanwhile was going on.

11.28. Patient complained of pain across the front of the chest, then became restless, stretched out his arms, and had wide-staring eyes. He probably lost consciousness for a few seconds. The heart sounds remained steady, and there was no sign of cardiac dilatation. Injection stopped.

11.33. The whole condition had passed off. Injection of saline containing serum resumed.

11.40. An urticarial rash began to appear on the arm, apparently along the line of the vein into which the fluid was being injected. Within a few minutes urticarial patches had appeared also on the forearms, hands, and the upper part of the trunk. They were not observed elsewhere.

11.55. Injection stopped, the patient having had 1,200 c.cm., and being distinctly improved.

12 midnight. All traces of urticaria had disappeared.

The improvement was temporary. The patient vomited a good deal during the night, and died the next day.

Post mortem, there was found acute dysenteric inflammation of the great intestine, with much thickening, and haemorrhage into the mucous membrane. Only two inconsiderable ulcers were present. The stomach was much distended, and contained a large amount of greenish-brown fluid. There was great dilatation of the duodenum, which had a diameter equal to that of a normal stomach.

CASE III.

B. G., aged 28. Admitted to hospital on September 23rd, 1916, with gunshot wounds of the right thigh and a deep gunshot wound of the right ankle. The notes of his case had been lost in transit. After admission he was found to be suffering also from dysenteric symptoms, and *B. dysenteriae* (Shiga) was grown from a stool on September 25th. The temperature was high (103°), and he had very frequent motions. Within the next few days he became very thin, had a dry brown tongue, and spoke with difficulty. The condition of his wounds was unsatisfactory. On September 3rd intravenous saline was given at 2 p.m.; 50 c.cm. of antidysentery serum was put in the container along with the saline before the injection was begun. When not more than 50 c.cm. of the mixed fluid had been run into the vein the patient suddenly became very ill, with eyes staring and arms stretched out. His face was pale, and he had become unconscious. Breathing stopped for about thirty seconds. Within a few minutes he looked quieter, but he remained unconscious for about two hours, with a rapid pulse. In the evening he improved, and was able to answer questions. No rash was seen. He had a restless night, but was rather better in the morning. At 11 a.m. 1,100 c.cm. of saline solution, without serum, was given, without abnormal symptoms. There was a transient improvement, but he died next morning. *Post mortem*, there was a well marked dysenteric condition of the colon, with a few shallow ulcers.

These three were the only cases to show unusual symptoms among a large number, not all cases of dysentery, in which either serum, or saline solution, or both together, were injected intravenously. The possibility of the entrance of air along with the fluid can be excluded. In Case I no serum injections had ever been given previously, and though it is unusual for sensitization to occur while the injections are being continued, and especially within six days of the first, I do not see how the symptoms can be explained otherwise than as due to anaphylactic shock, especially in view of the two other cases. In Case II antidysentery serum had been given subcutaneously twenty-six days before. The rapid appearance and disappearance of urticaria is of interest, and especially its appearing first near the site of injection. This corresponds to what is found in cases of serum sickness, where frequently the rash is first seen round the site of puncture. The absence of further symptoms when the injection was resumed is what one would have expected. The dilatation of stomach and duodenum was probably not due to anaphylaxis. In Case III there can be no doubt that the patient

had received a routine injection of antitetanus serum after being wounded, though this was overlooked at the time.

The most striking points about the cases are the rapidity with which the phenomena followed the injection of serum and the occurrence of severe pain in the chest as one of the first symptoms. Overfilling of the right side of the heart, such as might be caused by the too rapid injection of fluid into a vein, will produce precordial discomfort rather than pain. In Cases II and III the injection was not unduly rapid, and in Case I, from a mechanical point of view, the amount of fluid which entered the vein was negligible.

GRAVE DIABETES MELLITUS WITH PULMONARY TUBERCULOSIS FOLLOWING MUMPS.

BY

F. B. GILHESPY, M.R.C.S., L.R.C.P.LOND.,

TEMPORARY SURGEON, ROYAL NAVY,

AND

H. S. HOLDEN, M.Sc.,

TEMPORARY BACTERIOLOGIST, ROYAL NAVY.

As few cases of this sequence of events appear to be on record, the publication of these notes is perhaps justified.

The patient was a boy in the Royal Navy, aged 16½, undergoing training in a harbour ship. In May, 1916, he had an attack of mumps without any testicular or abdominal symptoms. On the third or fourth day of the disease the other boys in the ward started to tease him on account of his thirst (and remonstrated with him for drinking their lemonade). This drew his attention to the quantity of fluid he was drinking, but, independently of this, he noticed that he was passing urine three or four times during the night, which he had never done before. When first seen in Plymouth Hospital he had well marked symptoms of diabetes mellitus, with physical signs pointing to implication of both lungs with tuberculosis. On a dietary consisting of four ounces of bread and including green vegetables, but no other carbohydrate, ninety ounces of urine were being passed daily, with a total glucose output of seven ounces. The ferric chloride test for diacetic acid was markedly positive. On an initial starvation diet, with subsequent addition of carbohydrates to his fare, the patient's diabetic symptoms disappeared, except for the occasional appearance of slight quantities of sugar in the urine; calcium oxalate crystals could always be found. The disappearance of the glycosuria may be correlated with the presence of rapidly advancing tuberculosis of both lungs and with persistent evening rise of temperature to 101.5° to 102° F. The patient died five months after the attack of mumps.

NOTES BY H. S. HOLDEN, M.Sc.

Post-mortem Examination.

The left lung showed old extensive adhesions. The right was similar and, in addition, firmly adherent to the diaphragm. Both were very collapsed and showed massive lobar caseation, with breaking down at the apices. The mesenteric glands exhibited extensive tuberculosis, parts of the mesentery resembling bunches of grapes. There were a few tuberculous ulcers in the stomach, one about the size of a pea on the anterior surface of the pyloric end. The intestines showed a certain amount of tuberculous ulceration in all portions, this being most marked towards the lower end of the ileum. The liver showed slight fatty change.

Heart, kidneys, spleen, and brain were normal.

The pancreas was normal in appearance and weight (80 grams), but slightly soft in consistency. No anatomical peculiarity was found in the relations of its ducts.

Microscopic Examination of the Pancreas.—Sections were prepared from the head, body, and the tail of the gland, but those from the first two of these revealed little abnormality apart from a relatively slight round-celled infiltration in the more superficial portions. The sections from the tail, however, were of considerable interest, as, in addition to the infiltration, some of the islands of Langerhans showed evident hyaline degeneration, first described by Opie.¹ The affected islands were relatively scanty, although some of the remainder appeared to show slight signs of a similar condition.

REMARKS.

Abdominal symptoms have been but rarely described in mumps. In the course of an epidemic of thirty-three cases of mumps described by Edgecombe,² five of the subjects were affected by symptoms pointing very definitely to an implication of the pancreas in the disorder. Other writers have noticed the same train of symptoms occurring in the course of epidemics, and Morley Fletcher,³ summing up their evidence, states that severe abdominal pain starts within a week of the onset of mumps—usually the fourth

or fifth day—and is accompanied by vomiting and diarrhoea. The pain is usually epigastric, and tenderness above the umbilicus, with the presence of swelling or a diffuse resistance, can often be made out. The temperature hardly ever rises above 102° F., and the pulse-rate is not generally increased, and is frequently slowed. The immediate prognosis is good, and the patient is usually free from abdominal symptoms within the week. The same writer goes on to say, "some cases of diabetes may date their origin from inflammatory changes brought about in the pancreas by an attack." In favour of this cautious new opinion he quotes Barbieri's case of transient glycosuria in a boy of 6 years of age, in which the glycosuria followed mumps, but sugar disappeared from the urine in twenty-five days. Harris⁴ reported the onset of diabetes with acetoneuria in a man aged 42 years, the symptoms being noticed one month after mumps.

When it is remembered that the islands of Langerhans are found in relatively small numbers in the head and body of the gland as compared with the tail, it seems probable that the disturbance of the islands in the tail, described above, is enough to prove this to be a case of diabetes of pancreatic origin. In several recorded fatal cases of diabetes in which hyaline degeneration was present the number of islands affected was small and no other lesion which could have accounted for the symptoms was found. Very little evidence of previous inflammatory mischief was found in the gland in this case, which fits in with the clinical history, where no abdominal symptoms were noted. I can find no evidence in the literature of similar coincident changes occurring in the pancreas during an attack of mumps, as the clinical histories and *post-mortem* findings always pointed to an acute or subacute inflammation of the organ having taken place.

Owing to the severe nervous strain imposed by war it might naturally have been expected that diabetes, which has been experimentally shown to be associated with hyperactivity of the chromaffin system, would have become more frequent. From a careful analysis of the numbers of cases of diabetes treated at the Royal Naval Hospital, Plymouth, from 1911 to June, 1916, this expectation is justified. Out of 9,127 cases admitted to this hospital during 1911, 1912, and 1913 there were 5 cases of diabetes, or 0.05 per cent.; whereas out of 7,968 cases admitted during 1914, 1915, and up to June, 1916, there were 22 cases of diabetes, or 0.27 per cent. Assuming that the navy increased from 150,000 men in peace time to 350,000 in June, 1916, and has thus increased slightly more than twofold, the number of cases of diabetes admitted to Plymouth has increased fivefold.

I have to thank Fleet Surgeon R. St. G. Bond, Royal Navy, for his permission to publish this case, which occurred in one of his wards.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE TREATMENT OF DYSENTERY, WOUNDS, ETC., BY A COMBINATION OF INTERNAL ANTISEPTICS.

MAY I to bring to notice a mode of treatment the result of twenty-five years' experience in the Persian Gulf and India, where dysentery is endemic during certain seasons of the year? The patient is given a rectal injection of powdered ipecacuanha gr. xxx with m xx to xxx of tincture of opium every morning, and is placed on a mixture of carbolic acid and quinine. The nauseating and depressing effects of ipecacuanha given by the mouth are thus avoided, and the combination of carbolic acid and quinine, with its intensive bactericidal action, circulating through the site of ulceration, soon produces a development of new capillaries (as shown by the appearance of streaks of bright blood in the ejecta), together with the throwing off of the old sloughs. This beginning of improvement appears about the tenth day of treatment, and proceeds to the entire healing of the lesion. It is as

effective in chronic as in recent cases of the disease, and I have found it successful in a case of two years' standing. Of late years, however, I have discarded the injections, and have obtained as good results from the internal administration of carbolic acid with quinine alone.

The prescription for an average case is as follows:

R Acid. carbol. liq. (B.P.)	℥xl
Quininae sulph.	gr. xxxij
Acid. sulph. dil.	℥ij
Glycerini	℥j
Aq.	ad ℥viij

Half an ounce thrice a day in water, or every four hours, for a time, if the case be severe. The mixture is as clear as water if made up as follows: Pour the glycerin into the bottle, then half fill the bottle with water; add the carbolic acid, and shake well together. Dissolve separately the quinine with the dilute sulphuric acid in about two ounces of water, and add this to the previous solution in the bottle, shake again, and fill up the bottle. The glycerin is not absolutely necessary, but is useful.

The amount of carbolic acid may be increased usefully and safely to 4 minims and the quinine to 4 grains in each dose in severe or chronic cases. I have not seen any ill effects nor any carboloria, though I have put myself on the mixture for long periods as a test. Apart from its germicidal action, the tonic property of the quinine is invaluable.

The combination was used and highly spoken of in the great plague of Hong Kong in 1894. In three subsequent severe epidemics in India, in which I used the maximum doses mentioned above, plus soakage of the glands in carbolic oil (1 in 30), it was possible to give to the Plague Commission figures of a convalescence of 75 per cent. The curative action of this combination was found to be the same in typhoid as in dysentery. Long ago my attention was called to the efficacy of this combination for malarial fever by the late Dr. T. Holmsted, I.M.S., and I was led to investigate through many years the results of increasing the strength of the dosage in the various germ diseases of the East. He used it in doses of one minim of carbolic acid with one grain of quinine. The efficacy of the combination can be easily demonstrated by treating two similar cases side by side, the one with quinine alone, and the other with the combination. There would appear to be some interaction between the two drugs resulting in an intensive effect.

Equally satisfactory results have been obtained in cases of septicaemia, erysipelas, puerperal fever, and carbuncles. Lastly, the way in which wounds heal when the patient is on an internal course of this combination is very remarkable. With wounds so severe and numerous as in the present war, when the great desideratum is a sufficiently powerful bactericidal antiseptic, which, while thoroughly permeating the deepest wound, will in no wise damage the ordinary vital processes of repair, I would earnestly plead with the profession for a trial of this internal medication by a combination of quinine and carbolic acid, simultaneously with the usual protective antiseptic dressings externally.

Stroud. L. W. SEYMOUR, M.R.C.S., L.R.C.P.

PITUITARY EXTRACT IN CONCEALED ACCIDENTAL HAEMORRHAGE.

JELLETT has stated that concealed accidental haemorrhage is the most serious accident that can happen to a pregnant woman, with the single exception of acute puerperal sepsis. The following case seems worthy of note because of its severity and of the fact that the patient undoubtedly owed her life to the administration of pituitary extract. The preparation used was pituitrin, manufactured by Parke, Davis and Co., and put up in ampoules of 1 c.cm. each.

The patient was a fairly healthy multipara, aged 40, nearly eight months advanced in pregnancy. Three days before I was summoned she received a severe kick on the abdomen from a child she was nursing; during the three succeeding days she complained of abdominal pain and gradually increasing faintness, but there was no external haemorrhage.

I found her lying in bed, semiconscious, in a state of extreme collapse, her face blanched, pulse scarcely perceptible, respiration sighing. There were no labour pains. The cervix was softened and the os admitted a finger tip. There was a slight sanious discharge. The abdomen was merely tense and tender, but from the history and condition I diagnosed concealed accidental haemorrhage. I sent for pituitrin, and gave a large saline enema and a hypodermic of strychnine. Two ampoules

of pituitrin were then injected intramuscularly. In less than ten minutes there was marked improvement of the pulse, and in twenty minutes labour pains began. Every thirty minutes from the first injection I gave another ampoule, and the pains became gradually stronger and lasted longer.

The membranes were ruptured when the os was fully dilated, and three hours after the first injection a living child was born. The placenta was readily expressed and with it large masses of blood clot. The uterus contracted firmly and there was no post-partum haemorrhage. The mother made a slow but uneventful recovery. The child did not thrive and only survived a fortnight.

In all, 8 c.cm. of pituitrin were given; it had no galactagogue effect in this case, doubtless owing to the excessive loss of blood. Had delivery been effected by accouchement forcé or by supravaginal amputation of the uterus by Porro's method, I feel sure that, considering her desperate condition, her chance of recovery would have been very poor.

Birkenhead.

WM. ARTHUR KIDD, M.B., Ch.B., L.S.A.

A CASE OF SARCOMA TREATED WITH COLLOIDAL COPPER.

ALTHOUGH this is a recent case, the result up to date has encouraged me to publish it.

In September, 1913, a lady, aged 72, discovered a small, pedunculated, freely bleeding growth on the posterior vaginal wall, about two inches from the margin of the skin. This was removed, a good sized raw surface being left to granulate. The pathological report said, "Mixed spindle and round celled sarcoma."

In the summer of 1914 there was a suspicion of enlargement in the perineum in the mid-line at the junction of the vaginal mucous membrane with the skin. For some four to six weeks there was doubt, then in a week there was rapid enlargement, and a globular subcutaneous lump the size of a large walnut was obvious. This was removed, and the pathological report was as before. Everything went well until the early summer of 1915, when there was a suspicion of swelling in the right inguinal region. After several weeks of doubt a rapid enlargement showed clearly that a number of the inguinal glands were affected. These were removed with as much of the surrounding tissues as was possible. The pathological report was the same as before.

In February, 1916, after a longish period of doubt, it was clear that the most external inguinal gland was affected, and it was removed; the pathological report was once more as before. In July, 1916, a swelling appeared in the right ischio-rectal fossa; after the same period of doubt as in the other recurrences this was removed with all the surrounding tissues, and proved to consist of two lymphatic glands. As the naked-eye appearances were the same as in the two former sets of glands no specimen was sent for examination.

In February, 1916, a slight irregularity was noticed at the margin of the liver in the anterior axillary line. It felt like a small dent, such as might occur from the pressure of corsets, and this it was considered to be. In July, 1916, examination under an anaesthetic showed that it had not altered since February, and the same view was taken as to its nature. The patient went on satisfactorily until the middle of November, when suspicions arose that the liver was enlarging, and the former dent now seemed to be a prominence. After a few weeks the doubtful prominence in the liver had become a large knobby lump. Within a week the margin of the liver was below a horizontal line joining the two anterior iliac spines and acute pressure pain began in the region of the seventh to the tenth ribs behind. As the patient had only a moderately full abdomen it was easy to see the outline of the liver and knob when she lay back.

She was given injections of cuprase every six days, a whole ampoule in the gluteal muscles. She also took liquor violae glucosidi (Gadd) during the course of injections. After two injections the pressure pain abated, and after four was gone. She was given eight injections, the last in mid-February, by which time it was clear that the liver was much smaller. Since then it has diminished in size steadily up to date, and the liver has caused no anxiety, although it acts badly at times, and she has had two slight attacks of jaundice. In May, 1917, there was a definitely enlarged inguinal gland, the innermost of the inguinal chain, which, after the usual period of suspicion, showed itself fairly suddenly and unmistakably. This subsided after four injections of colossal copper (Oppenheimer) into the adjacent adductor muscles.

It appears to me that, apart from the manifest improvement following a course of colloidal copper, there are several points of interest in this case which warrant the rather full account given of it.

Sherborne.

T. MACCARTHY, M.R.C.S., L.R.C.P.

A BILL providing that marriage licences shall not be issued in the State of New York unless the contracting parties are able to furnish sworn statements that they are free from insidious diseases was signed by the Governor of the State on May 16th, and immediately became effective.

Reviews.

MALINGERING.

THE work on *Malingering*¹ by two experienced authorities, Drs. BASSETT JONES and L. J. LLEWELLYN, will be especially welcome to the medical profession at the present time, for, as the authors state in the preface, malingering in the eye of the laity bids fair to become not only the *crux* but the *opprobrium medicorum*. Not only is this subject of national importance in respect to recent legislative innovations, but even more so in connexion with exemption from military service and the granting of pensions for war disablement. The war has made it one of the principal duties of the medical man to discriminate between organic diseases and functional disorders and to detect simulation of disease and exaggeration of symptoms.

The work is practical and very comprehensive, nevertheless we are rather surprised to note how little reference is made to the experiences gained in this war, in spite of the fact that the authors, on page 53, state that "our own experience of soldiers in the present war leads us to the conclusion that pure malingering is uncommon." The differentiation of true "shell shock" from "shell shy" is of very great importance at the front, and to a less degree in the military hospitals at home. On looking up the index, neither the word "amnesia" nor its English synonym "loss of memory" occurs; yet a consideration of the effects on memory in relation to malingering and head injury is of extreme importance. In a discussion on the relation of head injury to nervous and mental disease, opened by Dr. Mott at the Neurological Section of the British Medical Association at Birmingham in August, 1911, he pointed out, and cited cases showing, that commotio cerebri produces a retrograde as well as an anterograde amnesia; he emphasized also the importance of this in connexion with simulation and exaggeration in regard to compensation under the Employer's Liability Act. Experience in this war has shown that if a man describes with much minuteness of detail how the shell burst and what happened, it is highly probable he did not suffer concussion. In cases of true "shell shock," even without visible signs of injury, the patient, on account of the commotio cerebri, has a variable degree of retrograde amnesia, extending, it may be, from a brief period of time prior to the shock to the whole time he has been in France, or even his whole previous life. We fail to find any mention of amnesia in the discussion of the subject of concussion in relation to simulation of symptoms. That loss of power of recollection is of great importance is shown by the fact that it is a not infrequent happening for soldiers to be admitted to clearing stations and military hospitals simulating complete loss of memory, and consequently supposed to be suffering from effects of "shell shock." Some of these soldiers admitted to military hospitals at home were subsequently found never to have been out of the country; they were undoubtedly malingering. On the other hand, cases of genuine "shell shock" have been found wandering, and have been taken to a hospital unable to recollect anything or give any account of themselves.

The chapter on malingering in relation to the special sense organs should prove very useful in detecting simulated deafness and blindness. We observe that the reference to labyrinthine concussion in soldiers (*Journal de médecine de Bordeaux*, April, 1916) occurs in a footnote, and presume, therefore, that the book was completed before that date; this may explain the absence of references to simulation of "shell shock" and war neuroses, although the book has only recently been published.

To the busy practitioner, Chapters V and VI, dealing respectively with the diagnosis of malingering and the formation of a decision, will be found of especial value on account of the clear, precise, and practical manner in which the subjects are discussed. As the authors state, the special pitfall of the malingeringer is his tendency to overact the part. The advice given as to the manner of approaching and examining the case denotes the wisdom

of experience. The authors point out the necessity of approaching the case without any preconceived notion and of making a thorough examination; for undoubtedly more mistakes are made from not looking than not knowing. "A mistaken diagnosis of malingering may entail lamentable effects, for the moral character is unjustly aspersed and insult is added to injury." "The doctor must therefore take heed that his suspicion of malingering is not founded on incomplete examination, imperfect observation, or hasty inference." We agree that when a doctor is unable to arrive at a definite conclusion it is better frankly to own that a decision either way is impossible; we should then see less of the cross-swearing in the courts of law so derogatory to the reputation of the profession. When the medical man is convinced that he is dealing with a malingeringer it is wise, as the authors state, to let him down gently; in the case of soldiers it is better to examine the patient in a room by himself. Excellent advice is given as to the writing of the medical report, for it is necessary to exercise great caution in the conclusions expressed and the wording. When giving evidence, the witness should make his statements definite and, as far as possible, unqualified. He should avoid the use of ambiguous expressions and choose words that are in common parlance rather than technical terms which the jury would fail to understand. To exact questions he should return exact answers and should avoid any sign of bias.

Section 2, dealing with malingering in relation to the nervous system, will be found of great service, in view of the large numbers suffering from war neuroses, which in no essentials differ from hysteria or neurasthenia. We do not find any reference to the second sign of Babinski; with this slight exception the section is a very full and comprehensive account of simulation in relation to functional and organic disease of the nervous system.

A considerable amount of space is very properly given to malingering in relation to epilepsy and insanity. Simulation of epilepsy, especially anomalous varieties, in which automatism is the essential manifestation of the disease, is not an uncommon form of malingering to obtain exemption from service, discharge from the army, or to avoid punishment for absconding, desertion, or other crimes. The detection of this form of malingering is not always easy; some officers at the front have found hypnotism useful. In the chapter on insanity in relation to malingering, we observe, on pp. 295 and 296, several quotations from *Hamlet* which might lead the reader to think the authors believed Hamlet was mad, whereas Maudsley in his essay on *Hamlet*, "Body and Mind," says: "Let it not escape attention that the deliberate feigning of insanity was an act in strict conformity with Hamlet's character"; consequently we should rather have expected the melancholy Dane to have been cited as a typical example of simulation of insanity to attain an end by a highly intellectual but irresolute, self-introspective character.

Malingering in relation to accident and bodily diseases is next fully considered. The last chapter is devoted to measures for the restriction of malingering. But space prevents further allusion to these important subjects; it must suffice to state that they are very adequately dealt with. In conclusion we may say that the authors are to be congratulated on the production of a very comprehensive, interesting, and well-written book, which has been made more attractive to the reader by many quotations from the great authors, notably from that greatest of all delineators of human character, Shakespeare, thereby showing that the authors, from their experience, recognize that in the study and detection of malingering one of the principal aims must be, in the words of Bacon, "the scientific and accurate dissection of minds and characters and the secret dispositions of men."

A large number of English and foreign medical authorities are quoted, and since we believe this will come to be regarded as a standard medico-legal textbook on the subject of malingering, we trust that in the next edition a bibliography of the various authors whose writings are cited will be included.

The first edition of Sir JOHN COLLIE'S *Malingering and Feigned Sickness*² was very favourably reviewed in this

¹ *Malingering, or the Simulation of Disease*. By A. Bassett Jones, M.B. Lond., and L. J. Llewellyn, M.B. Lond. With a chapter on Malingering in Relation to the Eye, by W. M. Beaumont. London: William Heinemann, 1917. (Roy. 8vo, pp. xxii + 708; 5 plates. 25s. net.)

² *Malingering and Feigned Sickness*. With Notes on the Workmen's Compensation Act, 1906, and Compensation for Injury, including the leading cases thereon. Second edition, revised and enlarged. By Sir John Collie, M.D., J.P. London: Edward Arnold, 1917. (Demy 8vo, pp. 664 + xvi; 78 figures. 16s. net.)

JOURNAL in April, 1913; it is therefore unnecessary to do more than allude to fresh matter which has been incorporated in this, the second edition.

Sir John Collie, from a large experience of neurasthenia gained during the war, now recognizes that the subject was not dealt with as fully as its importance deserves. No doubt previously he had had to deal with many cases of malingering or of conscious exaggeration masquerading as sufferers from traumatic neurasthenia; possibly he now sees the disease from a somewhat different point of view. He states that "neurasthenia, or 'nervous exhaustion,' is essentially a mental state, but has always some bodily disorder associated with and underlying it." But is not this statement somewhat misleading? We agree with Dejerine, who holds that the mind is primarily affected, and that if the body is not healthy it is in consequence of the affection of the mind. The author, in discussing the various systems affected—cerebro-spinal, cardiac, gastric—omits to mention one of the most important, the sexual.

We entirely agree with him that a purely symptomatic therapy leads to the fixation in the mind of an idea of a localized affection of the organ about which the patient complains, and is to be avoided, whether it be in a soldier or civilian who is suffering with neurasthenia. We note that he commences his chapter on hysteria by remarking that it is "a most fascinating disease," and undoubtedly it is a fascination to discover that a patient believed to be suffering with serious organic disease merely requires strong personal suggestion to effect a speedy cure. He points out that hysteria has much in common with neurasthenia on the one hand and with malingering on the other. "All these, when associated with traumatism, have this in common, that they are more or less curable by settlement of the claim, legal or otherwise." Doubtless Sir John has also found how frequently soldiers suffering with war neuroses rapidly improve with the tonic influence of an assurance that they will never be fit for the front again. In both instances a "judgement of value" influences the mind in action and conduct.

Although a good deal is said about the complement reaction of the blood in syphilis, we are surprised to find no mention made of the value of lumbar puncture and examination of the cerebro-spinal fluid as an important aid in differential diagnosis of organic from functional nervous disease. We may remind the author that this examination is especially valuable in differentiating incipient general paralysis following head injury from traumatic neurasthenia; an examination of the blood cannot do this, for a neurasthenic may give a positive reaction of the blood, though organic disease of the brain is not present. In fact, the complement reaction of the blood does not do much more than show that the man has had syphilis. A positive reaction of the cerebro-spinal fluid is a grave sign of disease, and does not disappear even after energetic treatment.

We confess to being rather disappointed with the chapter on military malingering for Sir John Collie must have had exceptional opportunities of studying "war neurosis" as President of the Special Board for Neurasthenia. Neither in this chapter nor in that on epilepsy do we find anomalous forms of epilepsy—"masked epilepsy" and malingering—discussed. Yet this is what the medical practitioner and army officer would look for and hope to find. Comparison of the signs and symptoms of the *grand mal* and simulation is given, and undoubtedly is useful, but the differential diagnosis is generally well known to medical men of experience. But even to the experienced and competent practitioner a difficulty exists in differentiating from malingering certain cases of "automatism" in which the question of criminal responsibility arises. The law, civil or military, requires evidence as to whether a person charged with a criminal offence was conscious of the quality of his acts, and it is a matter of frequent occurrence for soldiers to desert their posts, to abscond, or to be found wandering at large, who when questioned assert they have no recollection of what has happened for a certain time. Some of these are genuine cases of anomalous epilepsy, others are malingerers, who assert falsely that they have no recollection of what happened for a certain period of time in order to escape punishment. We venture to think that if Sir John Collie were called to give evidence at a court-martial he would not adhere strictly to the following dictum: "Personally, I never investigate the previous

history of a patient who is sent for medico-legal examination." Without an inquiry into the previous history, we should be liable to do grave injustice; but it must be borne in mind that a simulator knows that he can escape punishment for desertion by describing fits or attacks of *petit mal* "faints," especially when supported by a history of epilepsy in the family.

The author in many places emphasizes the fact that the simulator can usually be led on to exaggerate his symptoms, making the whole of his statement, if not absolutely untrustworthy, open to grave suspicion.

The second edition of this book can be cordially recommended for its medico-legal comprehensiveness, practical common sense, and robust diagnosis and treatment of malingering and feigned sickness. It is written in an interesting way, and the subject matter is largely based upon a varied and extensive personal experience in the detection of malingerers. But we are inclined to wonder whether the author is invariably as clever as the reading of the cases suggests. Is he infallible in diagnosis, and not mistaken sometimes regarding the mental attitude and feelings of "his friend the British workman," to whom in the dedication he says he owes so much?

PHYSIOLOGY: KIRKES—HALLIBURTON.

A NEW edition of Professor HALLIBURTON's excellent and popular *Handbook of Physiology*³ would not by itself call for extended notice in these columns, as the work is too well known to need further description or comment; but the original book out of which this has grown has now passed through twenty-five editions, and the publication of the twenty-sixth edition of *Kirkes' Physiology*—to give it its old name—has tempted the publisher, Mr. John Murray, to tell something of its history in a prefatory note. The book first appeared in 1848. Its author was Dr. W. S. Kirkes, whose name is still honoured at St. Bartholomew's Hospital by a gold medal and scholarship. On the title-page of his *Handbook* Kirkes acknowledged his indebtedness to James Paget, and it was an open secret that the work was largely based upon the notes from which Paget's masterly lectures on physiology at St. Bartholomew's were delivered; its great popularity with students was no doubt due to the fact that it carried Paget's teaching far beyond his own lecture theatre. The fourth edition, in 1860, had William Savory's name as editor on the title page. Seven years later Morrant Baker became joint editor. In 1869 the book, which had hitherto been published by the predecessors of Messrs. H. K. Lewis, passed into the hands of Mr. Murray. By this time constant changes and revision had left little of the original matter untouched. Further extensive improvements took place in 1876, when Dr. Klein became associated in the work of revision. From the tenth to the thirteenth editions Mr. Morrant Baker and Dr. Vincent Harris periodically revised the work. Thus for the first fifty-eight years of its prosperity *Kirkes' Physiology* was intimately and uninterruptedly connected with the medical school of St. Bartholomew's Hospital. In 1896 the death of Mr. Baker and the retirement of Dr. Harris forced the publisher to seek a new editor, and at the suggestion of Sir William Gowers, Professor Halliburton was offered, and accepted, the post. Thenceforward the book took on new characteristics, and within a little while of its entry upon a new era of popularity it became known as *Halliburton's Physiology*, the name of "Kirkes" being preserved only in small type on the title-page. This was justifiable since the new editor had made the book his own. These biographical details are not out of place in a notice of the twenty-sixth edition of a textbook which has been a favourite with generations of students for nearly seventy years. In preparing the latest edition the author has found the usual difficulty with the Basle nomenclature, a subject with which Professor Keith deals in a trenchant letter published in this issue. In order to meet the needs of students Professor Halliburton, with some reluctance, has inserted after the old names the new ones within square brackets, and refrains from criticizing the B.N.A. terminology.

³ *Handbook of Physiology*. By W. D. Halliburton, M.D., LL.D., F.R.C.P., F.R.S. Thirteenth edition (being the twenty-sixth edition of *Kirkes' Physiology*). London: J. Murray. 1917. (Demy 8vo, pp. 959; 3 plates, 581 figures. 16s. net.)

NOTES ON BOOKS.

MR. LOWES DICKINSON'S latest work, *The Choice Before Us*,⁴ is a destructive criticism of war as an instrument of policy; it is the antithesis of Bernhardt's detestable doctrines. The argument is that war proceeds from wrong ideas and wrong policies, in which all nations have participated; and that this war will have been fought in vain unless it leads to a change of attitude in all governments and in all peoples. The author holds that the renunciation of militarism, while most needed in Germany and most difficult to effect there, can only be brought about by complete and radical reform in which every nation takes its share. Militarism is caused by the menace of war, and grows with every added preparation for war. The remedy is deliberate preparation for a durable peace.

Dr. E. O. JORDAN contributes a small volume on *Food Poisoning*⁵ to the University of Chicago Science Series. After considering the poisonous plants and animals most frequently met with in America, the author passes to a brief account of the mineral and organic poisons commonly added to food. He next considers—at some length for so small a volume—the principal food-borne pathogenic micro-organisms, their products and effects. Dr. Jordan notes that English investigators regard infections with *B. paratyphosus* B as distinct from the "true" food poisoning by *B. enteritidis* and *B. suis*, but he scarcely does justice to the large amount of work on paratyphoid infections carried out during the war. Speaking generally on bacterial food poisoning he makes the sound observation that in any given case the exact source of infection is often largely conjectural.

MEDICAL AND SURGICAL APPLIANCES.

An Apparatus for the Intravenous Injection of Salvarsan.

DR. M. J. ROWLANDS (Pathologist, Mile End and Bethnal Green Military Hospital, late Pathologist, Royal Victoria Hospital, Netley) writes: The apparatus I now use is a modification of Professor Welchmann's, with which I became familiar whilst working at the Virchow Institute, Berlin. Upon my return to England further experience in the use of that apparatus disclosed several weak points which it has proved possible to remedy, and Messrs. Allen and Hanburys, of Wigmore Street, W., have now made for me an instrument which I have found very satisfactory in practice.

The essential parts of this simple apparatus are the two-ball valves, the seating of which must be perfect. The function of the upper valve is to prevent blood being drawn from the vein when the piston of the syringe is withdrawn, whilst the lower valve prevents the return of the solution to the receptacle which contains it. The syringe is filled with solution once or twice until all air is expelled. The tube, which has a metal male portion, is next inserted into the socket of the needle. The piston of the syringe is then drawn in and out until the required quantity of solution has been injected into the vein. The apparatus is easily sterilized by boiling, and it can be carried in an ordinary

inside coat pocket. In the figure a glass cylinder is shown, but any kind of receptacle can be employed, such as a tumbler. The quantity of fluid to be injected can be nicely gauged within wide limits. For instance, if 600 c.cm. of salvarsan solution is prepared in a large glass flask, 100 c.cm. can be injected into six patients by simply changing the needle each time. The needle is so constructed that after insertion into any vein it will rest on the arm parallel with the surface. When working alone, the instrument can be easily manipulated, one hand being kept on the needle whilst the other works the syringe by means of the ring in the piston rod. I have found this form of needle preferable to any other pattern, both for entering the vein and for remaining in position after insertion.

⁴ *The Choice Before Us*. By G. Lowes Dickinson. London: G. Allen and Unwin, Ltd. 1917. (Demy 8vo, pp. 274. 6s. net.)

⁵ *Food Poisoning*. By E. O. Jordan. Chicago: The University of Chicago Press. London: The Cambridge University Press. 1917. (Cr. 8vo, pp. 125; 11 figures. 4s. 6d.)

A Dish for the Irrigation Treatment of Gonorrhoea.

MR. DUDLEY KENNARD, F.R.C.S. Edin. (London, W.C.), writes that he has been using for the last six years a small dish which greatly facilitates the irrigation treatment of gonorrhoea. It consists simply of a shallow oblong dish with a vent pipe at one end to which rubber tubing is applied and carried thence to a receptacle on the floor. The dish is placed between the thighs as the patient is lying on the couch, and all the fluid used is led to the receptacle. This obviates the emptying which has to be done several times during the operation if three or four pints of lotion are used; it is nearly impossible for any of the fluid to be spilled, and it also ensures the irrigation being done whilst the patient is on his back, the best position for this treatment. The dish has been made by Mr. J. H. Montague, 69, New Bond Street, W.

HEALTH OF MUNITION WORKERS.

(Concluded from p. 85.)

INDUSTRIAL POISONS.

THE handling of trinitrotoluol may produce unusual drowsiness, frontal headache, eczema, and loss of appetite. Generally the symptoms are at first slight, and, if exposure ceases, quickly disappear; but if the exposure is continued they tend to become more severe and are associated with cyanosis (ashen grey and livid colour of the lips), which may be accompanied by dyspnoea, palpitation, rapid weak pulse, constipation, vomiting, anaemia, pains in the limbs, jaundice, and bile-stained urine. In a few instances death preceded by profound jaundice has resulted. The production of dust and the escape of fumes into the air of workplaces should be prevented, overalls and gloves worn by all, and head-coverings by women. The employer is responsible for these working costumes being washed at least once a week, kept in repair, and hung apart from the clothes of other workers, and for providing adequate washing accommodation, soap and towels. Every explosive factory is required to have a canteen where hot meals can be obtained, and every worker must be supplied daily at the expense of the employer with one pint of milk, or cocoa with milk. A medical officer must be appointed to examine every worker once in every fortnight, and a woman welfare supervisor at all factories where women are employed. No person must be allowed to be in any workplace where exploder bags are filled or blocks are pressed for more than a fortnight without a corresponding period in work not involving contact with trinitrotoluol.

In an investigation of trinitrotoluol poisoning made for the Medical Research Committee, Dr. Benjamin Moore proved that the poison does not enter by the digestive tract, for quite large doses are tolerated when swallowed; nor as dust inhaled, but by the skin. The susceptible individuals are those in whom skin absorption is free. It is probable that the poison is fixed by the skin; it cannot be removed by washing with soap and water, but only by solvents such as ether and acetone. When combined in the skin its absorption into the blood continues after the worker is removed from the factory, and may lead to a fatal degeneration of the liver. In the case of any worker showing signs of poisoning the poison should be washed out of the skin (hands, etc.) by the solvents mentioned. The workers affected can be picked out before serious symptoms occur, by observing the dusky livid hue of the face and lips. The medical officer, therefore, should go daily among the operatives and remove any cases showing this symptom. It is difficult by the wearing of overalls and gloves to prevent absorption, because the workers soil their hands in taking these off and on, and get the dust within the gloves. It has been the custom to soil the surfaces of the shells in filling them and then cleanse them by rubbing with paraffin, etc. The shells become coated with a film of dissolved trinitrotoluol, which soils the hands, and it is the workers who clean up the spilt trinitrotoluol who especially suffer; the whole trouble thus arises from careless and uneconomic methods. Automatic filling should replace handwork wherever possible.

Tetryl (tetra-nitro-methyl-anilin) stains the skin and hair, and in susceptible individuals may cause troublesome eczema. Garments can be worn to prevent this, but susceptible individuals are put on other work. A mixture of two parts of castor oil and one of lanoline rubbed into the skin after washing helps to prevent eczema. Tetrachloro-ethane, an ingredient of the "dope" varnish applied

to the canvas coverings and tapes of aeroplane wings, being heavy, sinks to the floor. It produces drowsiness, loss of appetite, constipation, and pains in the stomach, and, in serious cases, jaundice, liver destruction, coma, and death. An efficient varnish has now been found which does not contain this ingredient.

WASHING FACILITIES AND BATHS.

While it is advisable that facilities for washing and baths should be provided in every factory, such provision is imperative where poisonous substances are manipulated, or where heat, dust, or dirt are present to an unusual degree. Much good work has been done in this direction in France and Belgium, and experience in England shows that where such facilities are provided the workers make good use of them. Hand-washing places should be strong and durable and simple. Where separate basins are used one should be provided for each five persons. If the trough system is adopted there should be a constant supply of water from taps or jets above, set at an interval of not more than five feet, at the rate of two to every five persons. Soap of the consistency of butter or jelly is supplied in small boxes about four inches square, fixed in convenient positions above the trough and kept locked. The soap is obtained by inserting the finger into a round hole at the bottom of the box. If the soap be strongly alkaline, as is necessary to cleanse hands soiled with oil in engineering works, some ointment should be used after washing. Separate towels should be provided for each worker, partly because each thus obtains a dry towel, and partly to diminish the danger of infection. The towels should be at least five square feet in area. The simplest bath for men is the shower or douche, the stimulating effect on the skin of the falling water being greater than that obtained by total immersion. For women who have difficulty in keeping their hair dry, or drying it after bathing, a horizontal spray fixed at the level of the shoulders, or obtained from a movable nozzle or ring on a flexible tube, is desirable. Hot as well as cold water should be laid on to baths and washhouses where men work in great heat; hot baths may prove an effective antidote to muscular rheumatism. Arrangements should also be made for drying clothes; this is usually not difficult when the building is heated by hot-water pipes. Washhouses and baths should be in charge of a person appointed to see to their cleanliness, under the direction of the welfare supervisor.

WELFARE SUPERVISION.

The Ministry of Munitions, acting on the advice of the Health of Munition Workers Committee, has set up a special welfare department. The success of welfare work in any factory depends on the personality of the supervisor. Persons possessing the necessary character and qualities are rare, and until recently no facilities for obtaining instruction were available. The right qualifications cannot perhaps be imparted by a university education, but, other things being equal, a refined educated woman is most likely to command the respect and sympathy of working girls. The choice of the right kind of supervisor for boys presents great difficulties. He must not be too old, and must have a temperament enabling him to enter into the troubles, ambitions, and fun of boyhood.

A welfare supervisor is required—

1. To be in close touch with the engagement of new labour, or when desired to engage the labour.
2. To keep a register of available houses and lodgings; to inform the management when housing accommodation is inadequate, and to render assistance to workers seeking accommodation.
3. To ascertain the means of transit and the length of time spent in travelling, to indicate the need of increased train, tram or motor service, or to suggest modification of factory hours to suit existing means of transit.
4. To advise and assist workers in regard to feeding arrangements, to investigate the need for the provision or improvement of canteens and to supervise their administration.
5. To investigate records of sickness and broken time arising therefrom, and in cases of sickness to visit, where desired, the homes of workers.
6. To investigate, and advise in, cases of slow and inefficient work or incapacity arising from conditions of health, fatigue, or physical strain.
7. To consider, particularly for delicate and young workers, all questions affecting health and physical efficiency, and to supervise the conditions of night work, Sunday work, long hours, and overtime.

8. To advise on means of recreation and educational work.
9. To investigate complaints and assist in the maintenance of proper discipline and general order.
10. To keep in touch with responsible organizations having for their object the promotion of the welfare of the worker.

The Factory Acts enforce a minimum standard of healthful workshop conditions. The aim of welfare supervision is to realize a maximum. The humanizing of industry will surely tend to increase a workman's self-respect and enlarge his capacity for independent thinking. Thus will come about that realization of the chivalry of labour for which Carlyle pleaded. High wages do not necessarily mean high cost of production, and long hours of labour do not always bring a corresponding increase of output.

The need of the country having made it necessary to require women and girls to leave their homes for work in certain defined areas, it has become the duty of the country to provide suitable housing for them, and to safeguard the health and morals of the exported workers. Before a woman or girl is taken from her home she should undergo a preliminary examination by a nurse, with reference to a doctor if necessary. Mothers of infants or families of young children should not be moved, and the farming out of children while the mother goes to work in a factory must be discouraged. Before the woman or girl is moved it must be seen that she has sufficient clothing and money—provided, if necessary, from a special fund—to meet the initial expenses. Loans can be refunded out of wages. The travellers should be seen off and met at the railway station, and a reception or clearing house should be provided for them until lodgings are secured. The clearing house should provide baths and a washhouse, afford good plain appetizing food, and a cheery welcome.

When the works are in towns, the residents are asked to respond to the call of patriotism by receiving munition workers. A register containing complete information of lodgings is needed, just as in the case of army billeting, and a standard of accommodation, food, service, and rates of pay must be laid down. A housing superintendent and assistants make the agreement, pay the rent of the employee, receive complaints, and remove difficulties. A register of all the lodgings occupied, and of the lodgers, is kept, and any change of lodging and any illness involving more than one day's absence from work notified. Hostels have been established in certain districts. It has been found advisable to provide separate self-contained cubicles and a sufficient number of small sitting-rooms in addition to the public rooms, since the girls soon tire of organized recreation and crave for rest and quiet. Freedom compatible with good order must be allowed, and much depends on the wisdom of the lady superintendent and her assistants. A sick-room in hostels or the establishment of a cottage hospital may be required. Special provision must be made for maternity cases, for many of the women may be unwilling to return home. A local committee is required to deal with them—get them into hostels (of the Church Army, Salvation Army, etc.), and to reform the workhouse lying-in ward.

Opportunities for wholesome amusement, refreshment, and recreation should be provided. Winter gardens and cafés are needed, and the use of public halls in winter, and parks and open spaces in summer should be obtained. Small clubs should be opened for the workers by societies, and hospitality offered by well-to-do residents on Saturdays and Sundays.

The national experience of Great Britain in modern industry is longer than that of any other people. It has shown clearly enough that false ideas of economic gain, blind to physiological law, must lead, as they led through the nineteenth century, to vast national loss and suffering. Industrial life in the future must be guided by the application of physiological science to the details of its management.

It will be seen that for the Ministry of Munitions and its Health Committee and Welfare Department the health of the worker means something more than freedom from disease; it means, among other things, the avoidance of the weariness which makes labour a pain. The labour of munition workers may be made to contain all the three great sources of pleasure in work—physical exertion short of weariness, interest in doing well work which it is not easy to do well, and the inspiration of a great cause.

British Medical Journal.

SATURDAY, JULY 28TH, 1917.

ANATOMICAL TERMINOLOGY.

WE publish elsewhere a letter from Dr. Arthur Keith which discusses a matter having a very direct interest for every medical man—the reform of anatomical nomenclature. It appears that much confusion has arisen in examination rooms and hospital wards from the introduction of a new system of naming the parts of the human body—a system known by the letters B.N.A. (*Basle Nomina Anatomica*). The system, as Dr. Keith points out, is German in origin, but we should be the last to offer that as a reason for considering the system unfavourably, or even of reviewing it in any captious spirit. The system, which has now been introduced in our most widely circulated manuals of anatomy, must be judged on its merits and demerits.

In any scheme of reform certain defects of a minor order are inevitable. We notice, for instance, that the suprascapular notch becomes the “scapular notch”; the artery related to the notch, formerly known as the “suprascapular,” is now named the “transverse scapular”; the nerve, however, retains its ancient name, suprascapular. The nerve to the rhomboids has been renamed the “dorsal scapular” nerve, while the dorsal scapular artery becomes the “circumflex scapular.” It is difficult to understand how such a confusion has been permitted to occur, much less to have been approved and adopted by a section of our anatomists.

The instances we have cited are not solitary; we could reproduce scores of them. The reformers, quite rightly in our opinion, wished to restrict the use of the word *maxilla* to the upper jaw and to speak of the lower as the *mandible*. The salivary gland lying under the mandible, which in this new system we should expect to be called “submandibular,” is still called the *submaxillary*!

The reformers would seem to have had a particular prejudice against everything relating to the teeth. We have been accustomed to regard the teeth as important structures, but the reformers are of a different opinion; they apparently regard the tooth-sockets as more important than the teeth themselves, for all the dental nerves are now named “alveolar.” The important nerve we were in the habit of naming inferior dental enters the dental canal at the dental foramen, accompanied by the inferior dental artery; we find that the nerve and artery are now named “inferior alveolar,” and that they enter at the “mandibular” foramen and course forwards in the “mandibular” canal.

It may be thought that such criticisms can be levelled only at the attempts to rename minor structures, but when we turn to important organs, such as the heart, we find the new nomenclatures equally inapt. “Auricle” and “ventricle” we have been in the habit of naming the pulsatile chambers of the heart; the French use corresponding terms. The Germans use *Vorhof* as the designation of auricle; hence in the B.N.A. *Vorhof* receives the latinized form of “atrium.” We have therefore to speak now of the auricle as the atrium of the heart and name what we called its appendix—*auricle*! We have always

supposed that the grooves in front of and behind the heart were happily named anterior and posterior interventricular. The B.N.A. reformers substitute anterior and posterior “longitudinal sulcus.” The auriculo-ventricular groove, about which there could be no doubt, now receives the ambiguous name of “coronary sulcus.” Our old friend, the septum ovale, becomes the “pars membranacea septi atriorum,” and the annulus ovalis becomes the “limbus ovalis.” The tubercle which Lower observed in the calf’s heart, but which has really no existence in the human heart, is named the “tuberculum intervenosum,” while a muscular column in the right ventricle is described as the “supraventricular crest”! One might as well speak of the eminence on the arm caused by the biceps muscle as the “crista bicipitalis.” The auriculo-ventricular orifices become the “ostia venosa,” although they have nothing to do with veins and only one of them with venous blood. Owing to a misunderstanding of the just use of the term, “conus arteriosus” has been applied to the infundibulum of the right ventricle.

If we turn to the new names for the diaphragm we find that we can only use them if we completely misunderstand the structure, action, and development of this important muscle. Indeed, the new system of naming is so bad that in his carefully and sympathetically written book on *The Basle Anatomical Nomenclature*,¹ Dr. E. B. Jamieson makes the following note when giving the equivalents for the crura of the diaphragm: “B.N.A. too detailed.” We also see from Dr. Jamieson’s introduction that he is fully aware of the defects in the B.N.A. system. In our opinion the defects are very numerous, for whichever part or region of the body we select we find that the demerits exceed the advantages offered to us by the new system. An ear surgeon recognizes six walls in the tympanic cavity, and has named them quite naturally and accurately, roof, floor, inner, outer, posterior, and anterior walls. It is his duty, if he accepts the system advocated by the supporters of the B.N.A. terminology, to name them “tegmental wall,” “jugular wall,” “labyrinthine wall,” “membranous wall,” “mastoid wall,” and “carotid wall.” Yet it is claimed that the new system demands less from the students’ memory than the old system!

In the region of the limbs a number of changes have been made which reasonable men can only regard as changes for the worse. We shall cite only one or two examples. No one had difficulty in using the terms internal and external ligaments of the elbow-joint or knee-joint. Why, then, should we now rename them with the clumsy titles “ulnar collateral” and “radial collateral,” “tibial collateral” and “fibular collateral”? Applied anatomy has been more developed in English-speaking countries than in any other. The only possible exception is France. In our practice we found it convenient to name the great nerve which perforates and supplies the triceps in the upper arm the musculo-spiral; its two terminal divisions we termed radial and posterior interosseous because of their relations in the forearm. We are now asked by B.N.A. enthusiasts to adopt the German manner of naming this great nerve trunk and to call it “radial” from the shoulder to the hand. In an equally arbitrary and unreasonable manner it is proposed to change the naming of the great sciatic nerve and its ramifications.

We do not hold a brief for our present anatomical nomenclature; it has many defects, and is without doubt capable of being greatly improved. We are not

¹ *The Basle Anatomical Nomenclature*. By E. B. Jamieson, M.D., Ch.B. (Edin.), Lecturer on Anatomy, University of Edinburgh. W. Green and Son, 1916. (6s. net.)

at all convinced that it would be a wise measure to remove all proper names from anatomical literature, although that course is being advocated by Dr. Keith. But we are quite certain that whatever changes are made should receive the approval of an authority duly representative not only of anatomists but also of all medical men, and that this authority should embrace representatives both of the home and overseas peoples. It would be a particularly happy event if anatomists representative of all English-speaking countries could devise such alterations as are agreeable and necessary. We cannot afford to allow the nomenclature of a basal medical subject to be subject to the caprice of a handful of enthusiasts. In the meantime, and until public affairs are in a more settled state, we would counsel British physicians and surgeons not to accept the B.N.A. as either a standard or British anatomical terminology.

PENSIONS AND GRANTS FOR DISABLED OFFICERS AND RELATIVES OF DECEASED OFFICERS.

EARLY in the war it was announced in the House of Commons that medical officers of the Territorial Force and Special Reserve, and those holding temporary commissions, their widows and orphans, would be entitled to gratuities and pensions on the scale and conditions then applicable to regular officers. A select committee was appointed at the end of 1914 to consider and report on pensions and grants for officers and men. Its third report, issued in September, 1915, dealt with disabled officers and officers' widows, orphans, and dependants. The committee held that the existing regulations were too rigid, and should be relaxed; that the rates of disability pension for junior officers should be increased; and that the scales of pension differing according to the circumstances under which the officer met his death should be made more elastic. The recommendations generally were in favour of greater liberality and greater flexibility. The committee recognized that officers not belonging to the regular forces would not in most cases have sufficient length of service to qualify for disability pensions, and they recommended that such officers if invalided for medical unfitness caused by military service should be graded according to the impairment of their earning capacity, and awarded pensions at the minimum rate for regular officers. The proposed modifications in the method of classification of disabilities and in the estimation of pensions and gratuities related "primarily to officers holding combatant commissions in the navy and army"; but the committee added that "the cases of other officers should be reviewed departmentally where necessary on similar lines." Royal Warrants dated November 26th and December 10th, 1915, amended the regulations for officers' retired pay, wound pensions and gratuities, widows' pensions, and allowances to the relatives of deceased officers in respect of casualties during the present war, but applied only to combatant officers, and it was stated that regulations for the retired pay, etc., of disabled medical, veterinary, and other officers would be made known at a later date.

The Ministry of Pensions has now issued the draft of a Royal Warrant¹ for the retired pay of officers disabled, and for the pensions of the families and relatives of officers deceased, and for the pensions of nurses disabled, in consequence of the present war.

The warrant consolidates and amends existing provisions for this purpose, in accordance with the Ministry of Pensions Act, 1916. The Minister of Pensions is appointed sole administrator and interpreter of the warrant, and is empowered to issue the necessary detailed instructions. The warrant applies to all officers, and their relatives, whose claims to retired pay, or grants, arise out of the present war, and it will have effect from April 1st, 1917. Claims which were dealt with, or arose, under previous warrants, if the terms of the new warrant are more favourable to the beneficiaries, will be reassessed retrospectively, and no grant will be reassessed to the disadvantage of an officer, or his dependants. Retired pay for disabled officers will be granted according to a schedule, in correspondence with the degree of disablement. The conditions under which grants and allowances will be paid are set out in Part I of the warrant. Part II deals similarly with pensions and gratuities to widows and children and other relatives of deceased officers. Such provision, it is noted, shall not be claimed as a right, but shall be given as a reward for the officers' services, and shall be conditional upon the worthiness of the relatives. Part III deals with pensions and grants to disabled nurses. Part IV defines certain terms used throughout the warrant. The word "officer" means a commissioned officer holding a permanent, temporary, or local commission in the Regular, Reserve, or Territorial Forces, who has served and been in receipt of military pay as such, during some period of the present war, but does not include an officer of the Indian Army or of the Dominion, Colonial, or Protectorate Forces, unless the terms of his service have been made to include the pension rights of the regular army.

The case of the R.A.M.C. officer appears to be covered, and since no specific reference is made to him in the warrant, it is to be assumed that he is on exactly the same footing as combatant officers in every respect. That this is intended seems proved by a footnote to the schedule of pensions, etc., to officers' widows and children, which states that "colonel" means a colonel "who has been employed as a substantive colonel if a combatant officer, or in the rank of colonel if a medical, veterinary, or departmental officer." For all disabled officers and nurses there are eight degrees of disablement, and the amount of retired pay, or additional pension, is on a descending scale according to the degree of disablement, and to the rank held. The rate of retired pay, or pension, or gratuity granted may be determined according to the temporary or acting rank held by the officer at the time he was killed, wounded, injured, or removed from duty in consequence of disablement. Temporary or acting rank is to reckon in cases of disease no less than in cases of wounds or injuries. Pensions and retired pay are the same for captains and lieutenants, but there is a difference of £110 in the widows' gratuity. Except as modified by the new warrant, the general conditions laid down in the Royal Warrant of December 1st, 1914, remain in force, and apply to grants made under the new warrant. The warrant follows to a large extent the general recommendations of the Select Committee, although the scales of payment are not identical. Retired pay of a temporary, Special Reserve, and Territorial officer, instead of being granted according to four degrees of impairment of earning capacity, will be assessed according to the degree of physical impairment on a scale of tenths. The two schedules to the warrant setting out the rates of retired pay to disabled officers, and of pensions, gratuities, and

¹ Cd. 3631. London: H.M. Stationery Office; to be purchased through any bookseller, price 2d.

allowances to officers' widows and children are reproduced with explanatory notes in the SUPPLEMENT (p. 19). The rates for the highest degree of disablement are more favourable than the present rates in all ranks. If the officer is killed in action, or suffers a violent death due directly and wholly to war service, or dies within seven years from wounds or injuries so received, his widow will receive a gratuity in addition to her pension, and an increased allowance for each child. Disabled officers of small means, and the widows of deceased officers, may be granted education allowances for children, while the case of the invalid and the motherless child also is provided for.

An important provision lays down that, in future, pensions to disabled officers will be the same whether the disability was caused by service, or only aggravated by it, while provision is also made for officers becoming disabled after the war by service in the war. Half his retired pay may be withheld from an officer who declines to undergo treatment certified to be necessary in his interests. An officer certified to need special medical treatment in a sanatorium, hospital, etc., may receive retired pay at the rate for the highest degree of disablement, and actual necessary medical expenses may be paid for him. Officers invalidated out of the army for medical unfitness not attributable to nor aggravated by military service may be granted a gratuity, which in special cases may reach £300. Finally, it is to be noted that the regulations for relatives other than the widow and children of a deceased officer are considerably extended and relaxed. So far as can be judged from a preliminary study of the warrant the grants and conditions generally are as liberal and elastic as could have been expected. Medical officers are placed on the same footing as other officers.

PROMOTION OF ARMY OFFICERS.

THE committee on promotion of officers in the Special Reserve, new armies, and Territorial Force, has issued a report containing recommendations affecting combatant officers of the three branches and also ex-regular officers of the reserve of officers or on the retired list, but stating that the question of promotion in the Royal Army Medical Corps, Territorial Force, requires further consideration, and will be the subject of a separate report at a later date. The reason given for the postponement of this matter is the urgency of the measures recommended with regard to the promotion of combatant officers. It should be noted that the report of this committee, although published last week, is dated May 9th, 1917, and it was not until June 13th, 1917, that the witnesses nominated by the British Medical Association were called to give oral evidence before the committee. On March 17th, 1917, a memorandum concerning the promotion of majors R.A.M.C. (T.F.) was forwarded by the Association to the committee, and a further memorandum dealing generally with the position, pay, and promotion of Territorial medical officers was forwarded early in May. In the second memorandum attention was drawn to the widespread feeling that these officers did not receive the sympathetic treatment they deserved; and a series of specific suggestions were made. The representatives of the Association who appeared before the committee in support of these memorandums, on June 13th, were given a sympathetic hearing, and were led to understand that the points submitted by them would receive careful consideration. We hope that the committee will issue its report on this matter without delay; and we trust that the case of officers of the R.A.M.C. Special Reserve will also receive sympathetic treatment, for we know from many communications received that there are anomalies and hardships in their terms and conditions of service which are a real source of grievance.

AUXILIARY MILITARY HOSPITALS.

THE report presented to the War Office by the Joint War Committee of the British Red Cross Society and the Order of St. John of Jerusalem for the year ending December 31st, 1916, has been issued. It embodies a detailed statement of expenditure at each hospital, arranged under the counties, and an actuarial report by Mr. Basil E. Mayhew, F.C.A. At a meeting of county directors, held in London on September 19th, 1916, under the presidency of Sir Alfred Keogh, questions relating to the working of auxiliary hospitals, the position of the Joint Committee to them, and the relation of the county directors both to the hospitals and to the military authorities were discussed. Sir Alfred Keogh urged on county directors the necessity of combining economy in establishment and expenditure with efficiency. He submitted figures showing the varying costs at auxiliary hospitals, taken from the accounts for 1915, and by way of illustration stated that in comparable hospitals the cost of food varied from 1s. 8d. to 2s. 11d. a day, and that of drugs from 3½d. to 1s. 4d. a day. In December the Army Council agreed to institute a grant of 6d. a day per unoccupied bed, in addition to the capitation grant which is made on the recommendation of the Joint War Committee of the British Red Cross and Order of St. John. To the date of the report 85 applications for increased capitation grants and 424 for unoccupied bed grants were considered and dealt with. On January 9th, 1917, "all auxiliary hospitals drawing capitation grants, except permanent civil hospitals and auxiliary hospitals administered by boards of guardians and a few special hospitals," were placed officially under the county directors. This increased the cost of the county directors' offices, and the Joint Committee made a grant-in-aid to meet this, and at the same time offered financial assistance towards the transport of wounded in the county. When, later on, the War Office demanded an all-round increase in the accommodation at the auxiliary hospitals, the Joint Committee enlarged the scope of its original offer so as to include, on certain conditions, the cost of the extensions. In some counties, it is said, full advantage was not taken of the powers conferred upon county directors by the War Office, and in some instances the supervision exercised by them left much to be desired. The inspection of the hospitals by the county directors also varied considerably, and it is recommended that in all counties a travelling quartermaster should be appointed to advise on prices, accounts, and organization, if experienced men can be found to undertake the work. The total number of auxiliary hospitals submitting accounts in 1916 was 1,038, as compared with 815 in the previous year, and some particulars of the accounts of all the 1,038 hospitals are given, but Mr. Mayhew's analysis is limited to 960, of which 953 are in England and Wales, and 7 in Ireland. The total cost of maintenance was £1,997,404, but to this has to be added £165,002 for building and equipment, and £42,678 for administration, rent, rates, etc., making a total of £2,205,084. The capitation grants received from the War Office towards maintenance amounted to £1,530,144, the difference (£674,940) being made up by voluntary contributions. The War Office contribution represents 76 per cent. of the total cost of maintenance and 69 per cent. of the total cost of the hospitals. Mr. Mayhew gives an abstract of the cost of maintenance in the various hospitals classified in three groups—the first, hospitals with not more than 25 established beds; the second, with more than 25 but not more than 50, and the third with more than 50 established beds. He finds, as was to be expected, that the larger the hospital the more economically it can be run, the one important exception being in the case of surgery and dispensary, mainly expenses due to the fact that the larger hospitals take the more serious cases. The economy, he says, is not only in expenditure, but also in the number of staff employed, in transport, and

in many other ways not apparent from the figures. The difference in money is not very great, the average cost per day being in the smallest hospitals 3s. 7.20d., in the second group 3s. 6.66d., and in the group of largest hospitals 3s. 5.98d., the average for the whole 960 hospitals being 3s. 6.36d. The cost at different hospitals varies through a very wide range, and Mr. Mayhew calls attention to the case of Derbyshire as an illustration of how the average working cost of a county may be upset by the uneconomical management of one hospital. The average cost for the county, before including an expensively-run hospital, was 3s. 5d. a patient a day; including this hospital it became 4s. 1d. a day. Certain private hospitals and hospitals for officers are not included in Mr. Mayhew's general analysis. The average total cost of a patient a day in the private hospitals, which are for the most part small, is 7s. 4d.; but this average is very much affected by the fact that the cost at the largest hospital—the American Women's War Hospital at Paignton, Devonshire, with 233 beds—reached 10s. 10½d. a day. The average total cost of a patient a day in the hospitals for officers is 9s. 5d., but ranges from 7s. 5d. to 21s. 8d. Mr. Mayhew states that at certain hospitals a few beds have been set aside for the accommodation of officers, but considers that on grounds of financial economy this practice is not to be commended.

PRECAUTIONS FOR FLYING MEN.

THE *Journal of the Royal Naval Medical Service* for July contains an interesting note by Mr. H. Graeme Anderson (temporary surgeon R.N., attached to the Royal Flying Corps Service), based on a lecture delivered to pupils at air stations. Flying, he says, is a question of an active, well-balanced, decisive mind, and a series of sound and quick reflexes, visual, auditory, tactile, muscular, and balancing. The most important is the visual, the normal time for which he puts at twenty-hundredths of a second. The time for the auditory and tactile reflexes he puts at fourteen-hundredths of a second. He points out that the reflexes are slowed down or disturbed if the pilot is physically or temperamentally unfit, or is suffering from any illness, worry, fatigue, or from the after effect of excesses in alcohol. He recommends flying men to avoid alcohol and to be careful about smoking, a habit in which he says most aviators indulge too much. He considers that their diet should be generous and nourishing, and that flying when hungry should be avoided. Goggles should be fitted with non-splintering glass, and the hands covered with loose-gauntleted gloves lined with lamb's wool; the field boot, which should be of soft leather, ought to be lined with the same material. The face, when there is a risk of frostbite, should be smeared with a thin layer of vaseline, which prevents loss of heat from the skin. A curious point noted is that as most aviators fly with the mouth slightly open they should see that teeth and gums are in a healthy state, for any local disease may be increased by the cold and rush of air. He describes two forms of air sickness, one akin to sea sickness, due to the rolling and pitching of the aeroplane in "bumpy" weather. It is very rare, although a pilot by doing steep spirals and "switchbacks" may produce it in a passenger. The other form of sickness occurs at heights of 10,000 ft. and over, and is caused by the rarefied atmosphere and lack of oxygen. After passing 10,000 ft. the cold is extreme, and slight buzzing in the ears, difficulty in hearing, headache, fatigue, and torpor occur. The headache continues for some time after landing, and sleepiness is very marked. On a rapid descent the deafness and buzzing in the ears become more acute, and severe earache may come on. To guard against this "altitude sickness" oxygen should be carried and inhaled slowly as a preventive when going to great heights, especially for any length of time.

THE OXFORD OPHTHALMOLOGICAL CONGRESS.

THE Oxford Ophthalmological Congress held its eighth annual meeting at Oxford on July 12th and 13th. Members assembled on the evening of July 11th at Keble College, where, as in former years, accommodation had been kindly provided by the college authorities. The congress was again indebted to Professor Arthur Thomson for permission to conduct its proceedings in the Department of Human Anatomy in the University Museum. The meeting, which was well attended, was opened with a short address of welcome by the Master, Mr. Sydney Stephenson. The subject chosen for discussion, "The correction of errors of refraction," was opened by Lieut.-Colonel Robert H. Elliot and Mr. Ernest Clarke. Dr. George M. Gould (Atlantic City, N.J., U.S.A.), who had accepted the invitation of the council to open the discussion, was unavoidably prevented from attending owing to the serious illness of Mrs. Gould, but the manuscript of his address was read. The morning of the second day was devoted to papers and demonstrations. A paper by Dr. Edridge-Green (London) on the relationship of the theory of vision to ophthalmology was discussed by Lieut.-Colonel Elliot, Mr. Harrison Butler, Dr. Stewart Barrie, Mr. Traquair, and Mr. Hern. Dr. George Young gave an interesting demonstration of his method of testing the colour threshold and its diagnostic value, and Mr. W. W. Sinclair described his experience of the test with especial reference to renal retinitis. Lieut.-Colonel Elliot showed lantern slides illustrating the direction in which the cataract may be dislocated by the coucher during the Indian operation. Dr. D. V. Giri read a paper on ring infiltration of the cornea in a case of purpura and made some general observations on the different forms of corneal infiltration. Captain Adams spoke on retrobulbar neuritis with especial reference to prognosis. In the afternoon some extremely interesting cases, which were afterwards fully discussed by the meeting, were shown at the Eye Hospital by Captain Adams; Dr. Giri and Mr. Cridland also showed cases. Mr. Johnson Taylor read a paper on local anaesthesia, and Captain R. J. Coulter reported a case of bilateral interstitial keratitis following injury to one eye, with especial reference to its medico-legal aspect. At the close of the discussion on July 12th Professor Sir William and Lady Osler entertained the members and their friends to tea, and the official dinner was held on the same evening at 8.15 in the hall of Keble College, when the Vice-Chancellor, the Very Rev. T. B. Strong, D.D., Dean of Christ Church, was in the chair.

CLOTHING, VENTILATION, AND TRENCH FEET.

IN a lecture delivered some time ago before the Royal Institution on the science of clothing and ventilation and the prevention of trench feet, Professor Leonard Hill began by contrasting our well clad and housed people with the Terra del Fuegians described by Darwin as enduring naked a climate worse than ours. "Nature, by making habit omnipotent and its effects hereditary," had fitted the Fuegians to the climate. Our people nowadays generally over-clothed themselves and weakened the defensive mechanism of the body against cold by over-coddling. The Channel swimmer, robust and well lined with the natural coat of cutaneous fat, and thickly smeared with grease to prevent maceration of the skin, had endured the sea-water as long as twenty-three hours, and yet water had 240 times the conductivity of air and over 3,000 times its capacity for taking up heat. The adaptability of body habit, on the one hand to exposure, on the other to over-clothing and hot atmospheres, was enormous. The vastly improved health, vigour, and manhood of recruits taken from desk, shop, or factory and put to hard exercise in the open air, showed how much ill health and deficient vigour arose from sedentary confined occupations. No less striking was the effect on children of open-air

schools; these should be made universal. Cerebro-spinal fever and similar respiratory infections (common colds, etc.) were spread by close contact of the carriers of disease with others in confined places. Those living an open-air life with great exposure to cold did not suffer from these epidemics. Exposure to cool moving air toned up the body through the cutaneous nerves, and led to the taking of muscular exercise to keep up the body heat. Thus metabolism was maintained at a high level, appetite and digestion kept vigorous, the breathing deepened, the circulation of the blood invigorated, and the abdominal organs massaged by the deep breathing and the muscular exercise. The sedentary confined worker, housed in tenements, suffered the atrophy of disuse, and missed the enjoyment of life that came from perfect physical health, and with appetite impaired was a prey to minor alimentary disturbances. With regard to ventilation, he said that the two things that mattered most were bacterial purity—that is to say, the prevention of the spread of infection by saliva spray from carriers of disease—and the maintenance of a proper and not monotonous rate of cooling of the skin. The freedom of the air from dust and irritating and unpleasant products of combustion, smoke, petrol fumes, and smells that depress the feelings, was also of importance, but of minor importance. Indoors, what was wanted was a source of radiant heat and cool air, gently wafted first this way and then that, to prevent monotony or unpleasant draught. The open coal fire or the modern gas fire gave radiant heat, and reversing fans could be used to give changing wafts of air. The hot-air plenum system gave entirely wrong conditions. With the kata-thermometer, described in the section of the article on the health of munition workers, published last week, p. 84, Professor Hill demonstrated the enormously greater rate of cooling in cold water as compared with that in air of the same temperature, and showed the influence of a woollen glove containing entangled air compared with that of a glove wet and containing no air and that of a waterproof glove. Trench feet occurred in soldiers immersed in cold water for many hours. Bacterial decomposition of the skin secretions took place if boots and stockings were worn continually for days, and the skin was macerated by the ammoniacal products. Water soaked into the macerated skin and caused local destruction of the tissues. Prolonged immersion in sea-water was endured by fishermen with impunity because of the salt, which prevented maceration of the skin—a question of difference of osmotic pressure. It was not, therefore, merely the prolonged chilling, but the soaking of water into the skin which helped to do the damage. Ointments made with antiseptics, such as salicylic acids and essential oils, had been used by the Italian soldiers, spread on cotton cloths and wrapped round the feet. Prophylactic discipline, directed towards changing the stockings, and drying and cleaning the feet, was of the greatest importance. The continuous pressure of the boot on certain parts helped to produce the injury. The provision of waterproof waders, and trenches properly built with planked pathways and water channels beneath, had prevented the suffering which British troops endured in the first winter of the war.

NASAL ANTISEPSIS.

THE discovery of an effective nasal antiseptic is a matter of interest to every one who is liable to the common infectious cold, but its importance has been greatly increased since it has been shown to be, at the least, highly probable that the infection of cerebro-spinal fever dwells in the nose and may be imparted by the nasal secretions, and, moreover, that the infection may be carried by persons who have recovered from the disease and others who have never developed any of its symptoms. In a paper published in our columns of June 30th last Dunham and Dakin described an antiseptic, dichloramine-T, and the preparation from it of an oily solution for spraying

the nasal cavities. These observers stated that they had not then been able to treat carriers of cerebro-spinal fever, although they had made encouraging observations on carriers of pneumococci and diphtheria bacilli. We learn that the test in the case of cerebro-spinal fever carriers has now been applied with success. Before using the oily solution the nose is cleansed with salt solution or with 0.25 per cent. aqueous chloramine-T solution either by spraying or irrigation. When the increased nasal secretion which this causes has subsided, the oily solution of dichloramine-T is applied with an oil atomizer, an endeavour being made to reach all parts of the nasal cavities with an abundant supply of oil. As it is not certain that the oil introduced in this way continues active for more than two hours, it must, if the treatment is to be intensive, be repeated at the end of that interval, and in any case at least four times a day at about equal intervals of time.

SIMULATION OF DISEASE.

WE publish this week two reviews of British works on malingering, and have brought together in the *EPILOGUE* a number of abstracts from articles in foreign medical journals which describe in detail some of the varied and devious ways of the malingerer in the Continental armies of to-day. To malingering is defined by Murray as "to pretend illness, or to produce, or protract disease in order to escape duty." The term has been in military use in this country for several centuries, but shamming sickness or injury is as old as the human race, and has long been noted among domestic animals. We have all laughed at the dog limping miserably on three legs in order to excite pity or shirk a winter's walk, and some of us have been annoyed by the pony dead beat after a mile or two on the outward journey but ambitious to do ten miles an hour so soon as his head is turned home. In the civil life of this country the Workmen's Compensation Act, and the legal liability of employers and railway companies for accidents, have elevated the feigning of injury and its consequences into a topic of special medical study; but until the second year of this war, when compulsory service was introduced, the military aspects of malingering received scanty notice. In countries, however, where a conscript army is an old institution, the simulation of disease, in order to evade military service or dangerous duty, has been closely studied for many years, and the war has only served to increase medical interest in the subject. The experience of recruiting boards, as revealed in the evidence before the Select Committee of the House of Commons, and recent prosecutions for the attempted production of arthritis by the injection of irritants, and of tachycardia by the administration of a well-known drug, have made it plain that practices which have been brought to a fine art on the continent must now be reckoned with in this country. It is the duty of the medical practitioner, therefore, to make himself familiar with what is already known on this subject, since pitfalls abound for the unwary.

RECRUITING.

THE alacrity with which the War Office accepted the suggestion that the work of recruiting should be handed over to a civilian body to find the men and ascertain whether they could be spared from their civil employment, and whether they were fit for any of the various categories of service the army required, is perhaps a measure of the difficulty of the problem in its present stage. It has been stated officially that it was not anticipated that more than about ten per cent. of the men coming under the Review of Exceptions Act would turn out to be fit for service in any capacity. Whether the Act was well drafted or not is now beside the question; it is on the statute book and must be carried out unless and until Parliament decides otherwise. The question as to the civilian body to which the work should be turned over does not seem to have been

decided. The work to be done has two aspects: the one is the calling up of men for medical examination, and the other is the organization of the best method of medical examination, which must mean some primary classification. In the French system, which has been suggested as a model, the first question to be decided is whether a man is physically and mentally suitable for any kind of military duty whatever, or whether he must be altogether rejected, either permanently or temporarily. The question what kind of military duty he is suitable for is decided later. The Local Government Board possesses no machinery for the calling up or for the medical examination of recruits; either such machinery would have to be created or the recruiting department of the War Office taken over. It has also been suggested that a suitable civilian body would be the National Service Department, which possesses local committees, and claims to be able to deal in the best possible way with large demands for labour in any vitally essential industry; but its local committees consist only of employers and employed, and its work is mainly concerned with substitution. Neither the Local Government Board nor the National Service Department possesses any organization for the medical examination of recruits, and the profession will read with satisfaction the decision, reported in the SUPPLEMENT, of the joint meeting of the Committee of Reference of the Royal Colleges of Physicians and Surgeons in England and the Central Medical War Committee on July 25th to point out to the Government that in any re-organization of the recruiting machinery it is absolutely necessary that, as regards the medical examination of men, the selection of doctors should not be left wholly in any local hands, but should be supervised by a central body, and also that the two bodies are preparing a scheme, for the carrying out of this selection under their auspices, which they will shortly submit to the Government.

SUPPLY OF COCAINE.

THE Defence of the Realm Regulations relating to the supply of cocaine have recently been amended. Prescriptions containing cocaine must in future be retained by the chemist for inspection if required, and must be marked "not to be repeated." In order to avoid friction between dispenser and patient as to the ownership of such prescriptions, prescribers should inform their private patients of these requirements. But prescriptions given for national insurance purposes on official forms provided by Insurance Committees are exempted by the regulations from this provision. It will also no longer be necessary for national insurance prescriptions on the official forms to indicate the practitioner's address and qualifications.

THE WAR COLLECTION AT THE ROYAL COLLEGE OF SURGEONS.

WE ventured to draw attention last week to the inadequate manner in which the interesting war collection of pathological specimens at the Royal College of Surgeons of England is displayed. We understand that it is now recognized that the collection has grown too large for the small room in which it is at present being exhibited, and that it has been determined to rearrange it in a larger room; but whether it will be considered desirable to risk its destruction by a bomb by placing it in one of the large museum rooms is a matter which will be decided by the College authorities. A number of additional specimens are now ready for display, and by October it is hoped to have a comprehensive collection on view, including not only actual specimens of wounds of all parts of the body and of the diseases and consequences of military wounds, but also of missiles, of the various means of treatment adopted by military surgeons, and the results obtained, so far as they can be accurately represented by drawings, photographs, casts, and models.

Medical Notes in Parliament.

Army Medical Examination Committee.

WAR OFFICE PROPOSAL FOR A CIVILIAN RECRUITING AUTHORITY.

WHEN the Committee resumed its sitting on July 23rd Earl Derby attended. Before his evidence was taken, the Chairman (Mr. Shortt, K.C.) read the following resolution which had been passed at a private sitting of the Committee on July 19th:

That the Chairman be authorized to inform the Prime Minister that the Committee are of opinion, in view of the evidence already taken, that a change of system should be made at once, and recommend that the whole organization of recruiting medical boards and of the medical examinations and re-examinations should be transferred from the War Office to the Local Government Board.

That the Committee are of opinion that, in order to restore public confidence, this change should be made at the earliest possible moment, and be not delayed until the Committee present their full report in accordance with their terms of reference.

The Chairman stated that after this resolution was passed he saw the Prime Minister, and then had interviews with General Geddes (Director-General of Recruiting) at the desire of the Prime Minister, and next with General Geddes and the Prime Minister together.

Lord Derby explained that he had had a brief talk with Mr. Lloyd George when the latter was passing from a car to enter a train. Lord Derby went on to say that he accepted the resolution, absolutely with both hands, and would desire the committee to go further in its recommendation, even if in so doing it went beyond the terms of their reference. He asked it to recommend that the whole of the recruiting should be taken out of the hands of the War Office and of the military authorities and entrusted to a civilian department. That he knew would be making a very big step, and he must be excused if he did not say that it should go to the Local Government Board or to any particular body or advise that it should be placed in the hands of a body formed *ad hoc*. He recognized absolutely that there were certain things that must be remedied. The resolution of the committee would to a certain extent, if carried out, remedy them, but would not, in his opinion, heal the whole of the wound. It should be a condition that a civilian body should find the men, and until the men had gone through various processes to ascertain whether they could be spared from their civilian employment, and whether they were fit for the various categories of service the army required, they should not come under the authority of the military. This was not a new opinion on his part. When he became Director-General of Recruiting in October, 1915, he did so really as a civilian, holding that it was the duty of a civilian organization to put what was known as "the Derby scheme" into force. That the idea he was now submitting was not new was shown by the fact that Sir Neville Macready, Adjutant-General, had put forward such a proposal some time ago. The matter had been talked over many times since, and some weeks ago he had discussed it with General Geddes, who told him it would be quite possible to change the whole recruiting from a military to a civilian basis. Lord Derby added that he did not say that under the new conditions there would not be needed some of the men now employed on the military recruiting machine, but if the transfer of these men was to be made from the military to the civilian side they must be lent, and must go as civilians. They must take off the khaki and put on black coats and become purely civilian. For a few weeks the recruiting department had been nominally attached to the National Service Department. Though the Committee, unless it obtained from Parliament larger terms of reference, could not recommend his full scheme, it might make a suggestion which would meet the circumstances. The witness was asked by the Chairman whether the Prime Minister approved of this proposal, and he replied that Mr. Lloyd George on the necessarily hurried statement of the scheme said "All right." Lord Derby added, in reply to a further question as to whether he submitted a proposal in his capacity as War Secretary, that he did and that he was supported by the two principal officers most concerned. He believed, therefore, that the proposal would carry weight with the Cabinet. Asked as to the time that would be taken for bringing it into operation, he said he thought that although it would be a big business it could be done within two months. Particularizing a date earlier mentioned Lord

Derby said that his conversation with the Adjutant-General on this subject took place at the beginning of April. In answer to the Chairman the witness expressed his willingness to send out an instruction pending a change to make absolutely clear that the civilian doctors on medical boards were not to be over-ridden by the military presidents. The Chairman thought that it was undesirable for the Committee to go further into the question of the scheme at that moment as Lord Derby promised to submit it, and said that while in his view it would be for the army to lay down categories for military service it would be for the civilian authorities to give instructions to determine the definition of those categories.

In the House of Commons on July 25th Mr. Shaw asked Mr. Macpherson whether, in view of Lord Derby's statement on the previous day, instructions would be given to military representatives on tribunals to adjourn pending appeals with regard to men classified B 3 and C 3 until the new policy was announced. Mr. Macpherson replied he had received notice of the question only a few minutes, and had not had time to consult Lord Derby. In any case it would not be for him to give instructions to the appeal tribunals; but he would consult the President of the Local Government Board. Mr. Hogge asked if Mr. Macpherson would see that no men were recalled and re-examined under the Review of Exceptions Act until the new authority had been set up. Mr. Macpherson said he would consider that.

In the course of the debate on the vote of credit, Mr. Macpherson referred to the new scheme of recruiting, and expressed pleasure that what Lord Derby had said had been well received—so far as he could gather—in the country. It should be realized, however, that it might be necessary to arm the new body with powers which no civil body had at present. The question of discipline was bound to come up, and it was not easy to take a power out of the hands of the military and give it to a civil body which had not by its nature been accustomed to matters of that sort.

EVIDENCE.

Lieutenant-General Sir James Wolfe Murray, General Officer Commanding-in-Chief of the Eastern Command since May, 1916, gave evidence on July 19th. The usual questions were asked, but the witness had not much direct knowledge touching the controversy as to circulars and instructions. The principal fresh feature of his testimony depended on a letter dated August 22nd, sent to him by one of the Under Secretaries for War. In this communication it was said that in the Eastern Command there had been over 800 cases in seven or eight months of men being discharged as unfit after they had been passed by the medical boards. The letter asked him to draw the attention of the medical boards to the matter, with a view to examinations being more thoroughly carried out. He replied, on September 14th, 1916, that as far as men invalided out of the army for heart troubles were concerned the matter had already attracted his attention. With regard to the 800 men, he pointed out that they represented only 0.5 per cent. of the recruits examined in the command between January 30th and August 31st—namely, 161,450. That, he said, put the matter in a somewhat different light, especially when it was taken into consideration that the necessity of obtaining a sufficiency of recruits had been impressed on all medical boards.

In reference to the Mill Hill Board, Sir James said that on the press complaints inquiry was made, and the investigating officers came to the opinion that the board was doing its work particularly well, in that it was exercising more discretion than, possibly, some of the other boards. While allegations were being made in the press that the board was accepting every man that came along, the Eastern Command were complaining that it was rejecting too many. The President of the Board explained that this was due to the men being unfit. The board had struck a bad stream of recruits.

Sir James Mackenzie, who gave evidence on July 23rd, referred to the difficulty in which medical boards were placed. Before the war military doctors dealt with men who were fit and who wanted to join the army. That was an easy matter. The State now required that individuals of impaired health should be recruited. Army medical men had not been trained to deal with men of that description, and the general practitioner, especially in industrial centres, had more experience in deciding whether a man was fit for certain work. He said that mistakes and differences of opinion were bound to occur. He spoke of the advance made in knowledge of heart murmurs; some doctors ignored this advance, and that was how it happened that sometimes a man who had been rejected was passed into Class A by a doctor who recognized that the

murmur in his case was of no importance. He would have no hesitation in passing a man into Class A if an innocent murmur was his only trouble. He had seen a lad of 18 rejected on account of heart murmur who was the leading athlete of his school, and the day after his rejection won a prize for running the longest race in record time. A man with a serious murmur would never get into the fighting line, as he would break down in training. A man who complained of shortness of breath, palpitations, etc., would not be put into Class A. The witness agreed that matters wanted clearing up. He thought there should be an inquiry by competent medical men to see where the mischief lay, so that they themselves could take steps to correct it. Asked as to the instruction that men should be passed not for the category for which they were then fitted, but for that for which they were likely to be fit in four months, Sir James said that no medical man would make such a classification—it was really impossible.

Dr. Albert Bentham, F.R.C.S., a member of the Mill Hill Medical Board, stated that the highest number of men examined in a day was 390. At the beginning the usual number was 300; the figure was reduced to 250, and in May of this year a second board was constituted, and the number of examinations limited to 150 a day. At Mill Hill the members of the board had been overworked, and that probably accounted for the mistakes.

Dr. James Hayward of Liverpool stated that on the board on which he acted the president sat in a room by himself, and the civilian doctors did not know what happened to the men. The witness said he had criticized medical boards because civilian doctors had allowed themselves to be misrepresented to the public by being parties to decisions given by the medical president. Heart examinations, he held, should take place in a separate room, and not in the same room as the one in which weighing, talking, and exercises were going on.

Surgeon-General Julian, who recently became D.D.M.S. of the Western Command, afterwards gave evidence, but had not much information to give. In reply to a question as to those men passed who had proved unfit, he said he did not blame the medical board. The men were placed in low categories, and with the present category there was a difference between the soldier and a man fit for the army. It did not follow that a man fit for the army was fit for a soldier.

Specially Skilled Medical Officers.—Mr. Watt asked whether there were not eminent medical men, some of whom had special recommendations for surgery by the Scottish War Emergency Committee, stationed at Salonica in convalescent dépôts, and other such places in Greece, where their skill was unutilized and where medical men of one or two years' standing could satisfactorily accomplish the work. Mr. Macpherson replied that the authorities were always informed of any special qualifications possessed by medical officers proceeding abroad. It rested with the General Officer Commanding to employ them where and how the authorities might consider them of most benefit to the service. It was necessary to have such men as were referred to in the question available in a theatre of war, where at any moment serious fighting might break out with severe casualties as the result.

Treatment of Sufferers from Shell Shock.—Mr. Stewart asked Mr. Barnes whether his attention had been drawn to an appeal for money issued on behalf of recuperation hostels for sailors and soldiers invalided from His Majesty's services with nerve strain, and signed "Frederick Milner," in which it was stated that men had been, and were being, invalided out of the service in large numbers, with no prospect before them but the workhouse or asylum, or a miserable existence as a burden to themselves and their relations; and whether this statement represented the position of these men. Mr. Barnes replied that he was aware of the appeal, but had ascertained that it had not been seen by Sir Frederick Milner. The terms of the appeal did not accurately represent the facts with regard to men invalided out of the service on account of nerve strain. Recognizing the special difficulties presented by neurasthenia and shell shock, a special medical board had been constituted to deal with all such cases and award pensions or gratuities to them. This board had set up branch boards in Scotland and Ireland, and members of it had been visiting at intervals some fourteen towns for the purpose of examining men reported to them. Cases of neurasthenia and shell shock invalided out of the service before the special board was instituted were entitled to be re-examined by the board at all times, and Local War Pensions Committees had been specially instructed to report to the board, with a view to re-examination, any case which in their opinion was not being suitably treated. All cases of men invalided from shell shock were granted either pensions or gratuities, but in either event they were entitled to treatment or training under Article VI of the Royal Warrant.

Provision had been made for their treatment in an institution with 105 beds at Golden's Green, and its accommodation was about to be increased by 50 beds; other suitable accommodation was being sought in the neighbourhood of London. On July 21st a hospital for 50 of these cases was opened near Belfast. At Leeds 100 beds were being provided, and at Leicester another 100. Men were also being sent on the recommendation of the special board to recuperative work on farms in Essex. He hoped by these institutions, increased to any extent that might prove necessary, to carry out with State funds the objects of the appeal to private charity referred to in the question. If there were any mental cases or any insane men as the result of shell shock or any other cause, they were suitably provided for. These institutions might happen to be lunatic asylums provided out of public funds, but these cases were not treated as pauper patients, but as private patients without taint of pauperism. They were paid for at special rates by the Government. Allowances were made to wives and children on the widow and children scale.

The Medical Board of the India Office.—Sir William Collins asked the Secretary of State for India what were the powers and duties and who were the members of the Medical Board of the India Office. Mr. Montagu replied: The duties of the India Office Medical Board are to report on the medical fitness or unfitness of such members of the Indian services or candidates for appointment to Indian services as the Secretary of State required to come before the board for examination. The board was at present composed of Surgeon-General Sir Havelock Charles, G.C.V.O., I.M.S. (ret.) (President), and Lieut.-Colonel J. Anderson, C.I.E., I.M.S. (ret.).

Pay for Men Medically Re-examined.—In the House of Commons on July 20th Mr. Macpherson, replying to Mr. Watt, said that men called up for medical re-examination received a whole day's pay and ration allowances, amounting to 2s. 9d. in all. Special instructions were issued on July 5th calling attention to the fact that all men were to receive this allowance, irrespective of the date on which they were called up. Mr. Wing asked whether when men were called up by the examination form on one day and had to go on a second they would have pay for both. Mr. Macpherson thought that a very reasonable request and promised to convey it.

THE WAR.

TREATMENT OF GUNSHOT WOUNDS OF THE KNEE.

SPECIALARZT FÜR CHIRURGIE DR. HADDAEUS, in describing the results of treatment in seventy cases of gunshot injury of the knee-joint, stated that it had been necessary to discard the aseptic methods of civil practice. Since all gunshot injuries were to be regarded as infected a return to the older antiseptic method was inevitable. Haddaeus at first used a 3 per cent. solution of carbolic acid for injection into the joint; in some cases no suppuration took place but in others this treatment failed. In several cases, moreover, considerable quantities of carbolic solution remained in the joint owing to the small size of the trocar opening. To meet this difficulty, after injection of the joint he made an incision through the trocar opening and thoroughly irrigated the joint. These cases almost always healed rapidly and without any inflammatory reaction. He accordingly adopted this as his regular method in severe cases. In slighter cases he used puncture without incision, using a large trocar and washing out the joint energetically. He had never seen any case of poisoning following the use of carbolic acid. From the intense hyperaemia set up within the joint by this method Haddaeus was inclined to attribute the antiseptic effect less to the bactericidal action of the solution than to the hyperaemia. He therefore attempted to increase the hyperaemic action by the addition of other agents. He found a 10 per cent. solution of iodoform ether specially active in this respect, a temporary contraction of the arterioles gradually giving place to intense congestion. In certain cases a 2 per cent. solution of collargol was employed with good results. It was employed, on account of its stimulating influence in the formation and organization of granulation tissue, for irrigation during the later stages, and appeared to be of value in promoting the closure of the upper recess of the knee-joint.

Haddaeus's procedure was as follows: In apparently simple cases of haemarthrosis, where the presence of a foreign body or of wound of the capsule could be excluded with some certainty, a large trocar was entered at the outer aspect of the joint, the blood allowed to flow out, and the joint distended several times with 3 per cent. solution of carbolic acid, the patella being raised to permit the fluid to reach the upper recess. The trocar was with-

drawn before completely emptying the joint, so that the fluid subsequently coming away might sterilize a possible infection of the puncture from the skin or the joint itself. The puncture was made under anaesthesia by ethyl chloride rather than novocain, since Haddaeus considered that the latter rendered the tissues more subject to be attacked by a spreading infection. The leg was then immobilized in a long Volkman's splint, with the knee left freely under observation.

In severe cases, with large contaminated wounds in the neighbourhood of the joint, or with fragments in the joint, or in which puncture with the trocar showed that the haematoma was already suppurating, or in which the capsule itself was wounded—in all such cases the joint was opened on each side by an incision into the upper recess. The wound edges and capsule were then held apart with hooks, and the joint cavity thoroughly irrigated with carbolic acid solution, the inner surface of the joint being at the same time vigorously swabbed and rubbed. Finally, 10 c.cm. of a 10 per cent. solution of iodoform ether was run into the joint and allowed to remain for a few seconds, and the limb put up in a Volkman's splint. In this way it was often possible to prevent an infection from becoming manifest or to arrest it. In 68 of Haddaeus's 70 cases, many of them infections of the severest kind, recovery followed.

Where the knee-joint was wounded from behind Haddaeus enlarged the wound in the capsule in order to gain free access to the joint. This generally sufficed, but in two cases it was necessary also to open the joint below the patella, the ligamentum patellae being split longitudinally and the apex of the patella excised. Haddaeus did not consider the bacteriological examination of the fluid contents of the joint at all equal in value, as an indication for operative treatment, to the clinical evidence of infection. Suppuration often followed in cases in which the aspirated fluid was sterile, the explanation being probably that the joint, originally sterile, became subsequently infected from the surrounding tissues.

Of the cases treated 63 recovered with a movable joint—that is to say, the joint could be voluntarily moved in some degree, and in many of them there was already good movement.

WAR NEPHRITIS.

PROFESSOR MAGNUS-ALSLEBEN,¹ in a paper on acute nephritis, observed among soldiers between January and October, 1916, states that the first twenty were under his observation only two to three weeks, the cessation of the most acute symptoms being the signal for drafting them elsewhere. It was then recognized that transport in this early stage frequently provoked acute exacerbations, and subsequently the patients were nursed in one place for two to three months. An immediate rise in the blood pressure did not always occur; among at least a third of his cases there was no appreciable rise. Yet this feature did not disqualify these cases for inclusion in the category of war nephritis, for the other signs of renal insufficiency—oedema, etc.—were the same as those observed in patients with high blood pressure. In about half of his cases the blood pressure was considerably increased (150 to 180 mm. of mercury). Within one to two weeks the blood pressure almost invariably fell gradually to normal, but an abnormally high blood pressure was still demonstrable after the other symptoms and the oedema had passed off. In most cases disturbances of the circulation and of excretion vanished quickly and completely. On the other hand, a trace of albumin and a few casts and red cells were often found in the urine for several months in spite of strict rest in bed. He saw only five cases of uraemia; it occurred as a rule in the period of increasing diuresis; venesection supplemented by saline infusion proved beneficial, and no death occurred. He considered that the amount of fluid given should correspond with the excretion of urine, and that the old fear that a scanty supply of fluid favoured retention of nitrogenous bodies was exaggerated. The diet should be rich in calories, poor in nitrogenous bodies and salts. Professor Magnus-Alsleben states that all recent German publications agree that war nephritis is not a new disease, but is the well known acute glomerular nephritis which is a common sequel to scarlatina.

¹ *Muench. med. Woch.*, December 12th, 1916.

Professor Beitzke and Dr. Seitz² have carried out the following investigations to ascertain whether war nephritis is a microbic disease or not. In thirty cases, terminating fatally, they examined serial sections of the kidneys stained with polychrome methylene blue and with Levaditi's silver impregnation. In two cases they found small coecal emboli, which had apparently originated in purulent, bronchopneumonic foci. The very fine Gram-negative rods often seen and the spirochaeta-like structures observed in three cases were evidently artificial, the results of the silver stain. Thus, in the majority of cases, no micro-organisms were found. In fifteen cases a bacteriological examination of the blood and urine was made, always with negative results. The blood examination also failed to show eosinophilia. The authors apparently attached no importance to small Gram-negative rods stated to have been found in urine-bouillon cultures in two cases. Intraperitoneal injections of urine and defibrinated blood were made from several cases into mice and guinea-pigs, four mice and two to four guinea-pigs being, as a rule, used for each case. At first half the number of these animals were chilled in ice water just before inoculation with a view to promoting the development of nephritis. But this procedure was abandoned when it was found that it alone was sufficient to cause albuminuria lasting several weeks. The animals which survived the inoculation were killed eight days to eight weeks later, and the liver and kidneys examined in the same manner as the kidneys of the patients dying of war nephritis. Most of the animals, particularly the guinea-pigs, showed more or less definite nephritis, but the chilled animals were not more affected than the others. Sections of the kidneys in several cases showed small Gram-negative rods, but these, again, were regarded as artificial, created by the stain. The authors conclude that their investigations failed to show an infectious etiology of war nephritis.

TUMOR ALBUS PYOGENES.

PROFESSOR A. TIETZE has described, under the name of "tumor albus pyogenes," an unusual form of chronic inflammation which at times affected wounded tissues and caused delay in healing. It occurred more especially in suppurating gunshot injuries of the bones and joints, and was characterized by great swelling of the capsule of the joint, and of the surrounding soft parts, which were converted into a gelatinous, oedematous granulation tissue, traversed by numerous sinuses. Fever was absent, and the discharge from the sinuses sterile. The appearances closely resembled those of the white swelling of tubercle, or the analogous condition more rarely met with in syphilis. In the cases in question, however, those diseases were excluded, and there seemed to be no doubt that the condition had its origin in the injury and the accompanying infection. The following case is an example of the condition:

A comminuted gunshot injury of the elbow-joint, with suppurative; excision of the joint. Observed a month later the infection was found to be quiescent, but several unhealthy wounds were present, and the whole region of the elbow had undergone marked swelling, causing a fusiform enlargement of the limb from the middle of the arm to the middle of the forearm. The swelling involved the soft parts only, the bones showing, by the x-rays, merely the changes resulting from the excision, and one or two fragments of the projectile. The ulnar nerve was paralysed, but was subsequently proved not to have been injured.

Tietze explained the origin of the condition on the supposition that while the infection ceased to be active, a formative irritation was set up in the damaged soft parts by small foci of necrosis resulting from the past infection, and by minute fragments of the projectile or bone implanted into the tissues by the explosive action of the injury. An examination of the parts removed in cases where excision had been performed appeared to support this theory.

The course of this very chronic process could not be accelerated to any appreciable degree by operation, since it was impossible to locate and remove the numerous foci of irritation present; there was, moreover, the ever-present danger of lighting up the quiescent infection through operative interference. It seemed preferable to limit operative measures to enlarging the existing sinuses where these appeared to afford an insufficient outlet for the

discharges. Tietze had, however, found that a rapid diminution of the swelling in these cases, with arrest of the chronic process and rapid healing of the wounds, followed the administration of potassium iodide.

HONOURS.

A SUPPLEMENT to the *London Gazette* dated July 18th contains a further list of awards to officers, non-commissioned officers, and men for conspicuous gallantry and devotion to duty in the field. The list includes the following medical officers:

D.S.O.

Temporary Captain James Harding Barry, M.C., R.A.M.C., attached London Regiment.

For conspicuous gallantry and devotion to duty in attending to the wounded under exceptionally trying conditions. Under very heavy shell fire he dug out five men who were buried, and amputated two men's legs on the spot. He showed utter disregard of any personal risk, and his example was splendid.

Major Lionel Wilfred Bond, A.A.M.C.

When in charge of advanced collecting and forwarding posts his total disregard of danger under a terrific hail of gas shells, H.E., and shrapnel fire gained him the confidence of all ranks and greatly assisted the evacuation of the wounded. Later, although wounded and partly gassed, he refused to leave his post, and his bravery and devotion saved a very critical situation.

Major Herbert Percival Brownell, A.A.M.C.

For conspicuous gallantry and devotion to duty whilst attending to the wounded under heavy fire. His coolness in organizing matters amidst the greatest confusion enabled the wounded to be expeditiously treated, and he personally treated some hundreds of cases under heavy shell fire.

Major Horatio Victor Patrick Conrick, A.A.M.C.

For conspicuous gallantry and devotion to duty in attending to the wounded. He proceeded to the scene of an explosion under very heavy shell fire, and personally directed the removal of the wounded. His fearlessness and disregard for his personal safety has been marked on all occasions.

Temporary Captain James Henry Fletcher, M.C., R.A.M.C.

He showed the utmost bravery and coolness when commanding the bearers. He worked continuously under artillery and machine-gun fire. It was largely due to his gallant conduct that so many wounded were safely evacuated.

Temporary Surgeon William James McCracken, M.C., R.N.

For conspicuous gallantry and resource during operations, when, after attending wounded in captured dug-outs, he pushed forward into a village which was being heavily shelled, compelled a captured enemy M.O. to show the best enemy R.A.P., and then kept him, with twelve enemy Red Cross men, busy all day bringing in and dressing over 150 of our wounded, who otherwise could not have been treated, and then sending them down. He also searched the front line under a heavy fire for wounded.

Bar to Military Cross.

Temporary Captain Charles Bromley Davies, M.C., R.A.M.C.

He was in command of the bearer division when evacuation was most difficult. He showed great gallantry and resource in pushing forward under heavy fire and rescuing several wounded men. (Military Cross gazetted August 25th, 1916.)

Temporary Captain James Churchill Dunn, M.C., M.D., R.A.M.C., attached Royal Welsh Fusiliers.

For conspicuous gallantry and devotion to duty in attending to the wounded. He crawled close up to the enemy's wire, accompanied by another officer, and brought in a wounded man on a waterproof sheet. (Military Cross gazetted August 25th, 1916.)

Temporary Captain Harold Garnett Janion, M.C., R.A.M.C., attached R.H.A.

He was assisting to remove the pilot from a wrecked aeroplane when the spot came under heavy fire from a hostile battery. Several of the bearers were wounded, but by his courage and example this officer collected fresh bearers and conveyed the wounded men to safety. This task was carried out under continuous shell fire. (Military Cross gazetted June 23rd, 1915.)

Captain Maurice Baylis King, M.C., M.B., R.A.M.C. (S.R.).

For conspicuous gallantry and devotion to duty in rescuing wounded under very heavy shell fire. His fearlessness set a splendid example to the stretcher-bearers, who were then much shaken by the heavy shelling. (Military Cross gazetted January 1st, 1917.)

Captain George Seabourne Robinson, M.C., A.A.M.C.

He displayed great courage and determination in attending wounded under heavy fire. On one occasion he personally led a party out in front of our line for the purpose of searching and attending the wounded not yet collected. (Military Cross gazetted June 4th, 1917.)

Temporary Captain James Lennox Stewart, M.C., M.B., R.A.M.C., attached Gordon Highlanders.

He behaved with the utmost gallantry in removing the wounded under shell fire. He continued to work in the open exposed to severe shell and machine-gun fire until every wounded man had been brought in. (Military Cross gazetted May 16th, 1916.)

Military Cross.

Temporary Captain Frederick Carson, M.B., R.A.M.C., attached Royal West Kent Regiment.

He behaved with the greatest gallantry in attending wounded under continuous heavy shelling. His total disregard for personal safety set a fine example to those around him.

Temporary Captain Henry Joseph Cotter, R.A.M.C., attached Lincolnshire Regiment.

Although wounded on the previous day, he declined to be relieved, and continued to dress wounded in the open under heavy fire, going through heavy barrage to reach some men lying out in an exposed position.

² *Berl. klin. Woch.*, December 4th, 1916.

Temporary Captain Albert Victor Craig, M.B., R.A.M.C., attached Royal Field Artillery.

Though suffering himself from the effect of gas shells, he displayed the greatest bravery and the most untiring energy in attending to the wounded under fire of heavy guns and gas shells. He risked his life day and night without the slightest hesitation.

Temporary Captain John Nissen Deacon, M.B., R.A.M.C., attached East Yorks Regiment.

He showed exceptional bravery and resource on several occasions in attending to the wounded under very heavy shell fire, with complete disregard for his own personal safety.

Temporary Lieutenant Cyril Duncan, M.B., R.A.M.C.

For conspicuous bravery and devotion in attending wounded close to a large ammunition dump which was on fire, with splinters and shrapnel shells flying about, and later, although partially gassed, attending wounded under heavy gas shell fire.

Captain Hugh Hart, C.A.M.C.

He displayed the utmost gallantry and courage in attending wounded continuously under heavy shell fire.

Temporary Captain James Duncan Hart, M.B., R.A.M.C., attached London Regiment.

He commanded an aid post close to a piece of heavily shelled road-way. He continually went out into the open road and attended wounded men under heavy fire, with a total disregard for his own personal safety.

Temporary Captain Charles Reginald Ralston Huxtable, M.B., R.A.M.C., attached Lancashire Fusiliers.

He showed the utmost skill and bravery in attending to and evacuating wounded. When seven of his bearers were buried by a shell he at once, despite the intense hostile bombardment, organized a party and dug them out.

Temporary Captain Charles Clouston Irvine, R.A.M.C., attached East Yorkshire Regiment.

He took his stretcher-bearers out under heavy barrage fire and brought the wounded back safely, carrying one man back on his shoulders. His complete disregard for his own personal safety was most marked.

Captain Cyril Jacobs, M.B., R.A.M.C.(S.R.), attached Lincolnshire Regiment.

After an assault he went out over the whole ground in daylight, cleared as many of the wounded as possible, and, having located the wounded who were in the enemy wire and close to it, completed his task by nightfall. He succeeded in evacuating all wounded men.

Temporary Captain Richard Orthin Hilton Jones, R.A.M.C.

For many hours he had to occupy a most exposed position under heavy fire, where he dressed and attended wounded at great personal risk.

Captain Douglas Ballantyne Kennedy, C.A.M.C.

He directed the work of the stretcher-bearers for forty-eight hours without rest, and repeatedly aided the wounded under very heavy shell fire.

Temporary Captain Francis Kenneth Kerr, M.B., R.A.M.C., attached Royal Scottish Fusiliers.

During heavy and accurate hostile fire he continued to dress wounded, although the building was hit several times. His fine example was of the utmost value to those around him.

Captain Charles Herbert Leedman, A.A.M.C.

Although he and several of his staff were wounded by the heavy shelling of his post by the enemy, he continued, with the greatest gallantry, to attend the wounded, remaining at his post until it became untenable.

Captain (now temporary Major) Ronald Hugh Macdonald, C.A.M.C.

One of our aeroplanes was shot down, the observer was wounded and pinned beneath the wreck. This officer and a bearer went out in full view of the enemy, who were shelling the machine, and extricated the wounded man and removed him to safety. He himself was severely wounded while doing so.

Temporary Lieutenant Joseph Randolph Morell Mackenzie, M.B., R.A.M.C., attached South Staffordshire Regiment.

For conspicuous bravery and devotion on numerous occasions when attending wounded and leading stretcher-bearer parties under every kind of heavy and continuous fire, and invariably exhibiting great skill, coolness, and contempt of danger.

Temporary Captain Randal Vivian McDonnell, R.A.M.C., attached Bedfordshire Regiment.

For over forty-eight hours he attended more than 200 wounded, many having to be dressed in the open under heavy fire. His total disregard of personal danger was beyond praise.

Captain Malcolm McGillivray, M.B., R.A.M.C.(S.R.), attached South Wales Borderers.

Although his dressing station was twice blown in, and himself extricated with great difficulty, he continued to attend wounded under heavy shell fire.

Temporary Captain Daniel McKelvey, M.B., R.A.M.C., attached Gordon Highlanders.

During an attack by his battalion he followed them closely and attended to the wounded in the open under very heavy fire. His fearlessness and gallant conduct throughout the operations was most marked.

Temporary Captain Murdo McKenzie McRae, M.B., R.A.M.C., attached Northumberland Fusiliers.

Owing to the shortage of bearers this officer carried in during the night seven or eight wounded men who otherwise would have died in the snow. He has performed consistent good work throughout.

Captain Robert James Manion, C.A.M.C.

While going forward through a heavy hostile barrage to establish an aid post he at great personal risk stopped and dressed alone nine wounded men.

Temporary Captain Arthur Gilbert Michelsen Middleton, R.A.M.C.

He showed great gallantry and bravery in carrying in two wounded men under heavy hostile shelling. He displayed the utmost disregard for danger throughout in carrying out his duties.

Captain Cyril Charles Minty, A.A.M.C.

He showed the greatest courage and fearlessness in attending wounded whilst exposed to heavy shell fire and gas fumes, and assisting to carry them to the collecting post. The stretcher-bearers had suffered severe casualties, and it was owing to his magnificent example that they maintained their courage and endurance.

Temporary Captain George Lynn Pillans, R.A.M.C.

He showed great determination and courage in leading bearer squads through heavy barrage. This he did several times, and throughout superintended the evacuation under heavy shell fire.

Temporary Lieutenant Joseph Rickards, M.B., R.A.M.C., attached Royal Scots.

He attended a large number of wounded in a barn which was under heavy shell fire. During the night he organized a party which brought in many wounded from an exposed position on the battlefield.

Temporary Surgeon James Ness McBean Ross, R.N.

For conspicuous gallantry and devotion on many occasions in organizing and leading stretcher-bearers in search for wounded, and attending them under very heavy fire.

Temporary Captain John Finlayson McGill Sloan, R.A.M.C.

His dressing station being blown in on the top, he dressed over 200 cases under very difficult conditions. He had to twice change his dressing station.

Temporary Lieutenant (temporary Captain) Harry Neville Stafford, R.A.M.C.

Having received a message that many wounded were on heavily-shelled ground, he organized rescue parties, and brought them all in, although he was severely wounded in this gallant work.

Temporary Captain Charles Gordon Timms, R.A.M.C., attached Royal Fusiliers.

For two days he attended the wounded in the open under heavy and incessant shell fire, quite regardless of personal danger, and his coolness and energy alleviated much suffering.

Temporary Captain William Annandale Troup, M.B., R.A.M.C., attached Wiltshire Regiment.

He displayed the utmost skill and endurance in clearing the wounded between the lines after the attack. Through the day he carried out his task under continuous shell fire, and was thus instrumental in saving many lives.

Captain Alexander Guthrie Semple Wallace, M.B., R.A.M.C.(S.R.), attached Royal Lancaster Regiment.

He continued to attend wounded men in the front line trench despite hostile bombardment. His total disregard for personal danger set a fine example to those around him.

Temporary Captain Robert Bruce Wallace, M.B., R.A.M.C., attached Leicestershire Regiment.

For conspicuous bravery and devotion on many occasions, and notably when suffering from a painful wound he not only continued to dress wounded but went out with stretcher-bearers under heavy fire and dressed and brought in men unable to move.

Temporary Captain Donald Alexander Warren, R.A.M.C., attached Royal Warwickshire Regiment (Lieutenant C.A.M.C.).

He continued to attend wounded for over an hour under heavy artillery and machine-gun fire and in full view of the enemy. Later he established an aid post, and carried on for forty-eight hours without rest under continuous fire.

Temporary Captain Philip James Watkin, R.A.M.C., attached Bedfordshire Regiment.

For two days he dressed wounded under heavy shell fire, and, when the captured trenches had been cleared, he commenced to search the shell holes in "No Man's Land," in spite of heavy sniping fire, until ordered to desist.

A bar to the Military Medal has been awarded to one non-commissioned officer of the R.A.M.C., and two non-commissioned officers and two privates of the A.A.M.C. The Military Medal for bravery in the field has been awarded to Sister L. E. James (Queen Alexandra's Imperial Nursing Service), Acting Sister E. Maude (Queen Alexandra Imperial Military Nursing Service Reserve), twenty-four non-commissioned officers and seventy-two privates of the R.A.M.C., thirteen non-commissioned officers and twenty privates of the A.A.M.C., two non-commissioned officers and two privates of the C.A.M.C., and five privates of the S.A.M.C. The Distinguished Conduct Medal is awarded to two non-commissioned officers and one private of the R.A.M.C.

MENTIONED IN DISPATCHES.

A supplement to the *London Gazette*, issued on July 21st, contains a list of officers, warrant and non-commissioned officers, men, and nursing staff of the British Salonica Force brought to notice by Lieutenant-General G. F. Milne for distinguished service during the past six months. The following medical officers are mentioned in the list:

SALONICA.

Army Medical Service.

Temporary Colonel F. D. Bird, C.B.

Royal Army Medical Corps.

Lieut.-Colonels (temporary Colonels): J. C. Connor, C. T. K. Maurice, C.M.G., P. MacKessack.
Lieut.-Colonel J. R. Whit, M.B.
Majors (temporary Lieut.-Colonels): L. L. Fisher, A. E. Kidd, J. Matthews.

Majors: F. J. Garland, P. H. Henderson, D.S.O., E. B. Waggett, W. J. Weston, R. K. White.

Temporary Majors: K. W. Monsarrat, H. Wiltshire.

Captains (acting Lieut.-Colonels): P. G. M. Elvery, M.C., B. Johnson, A. D. O'Carroll, G. H. Stevenson.

Captains (temporary Majors): C. M. Fegen, W. D. Sturrock.

Captains: D. V. M. Adams (Res. of Off.), J. H. Beverland, T. Carnwath, C. Clarke, D. M. Corbett, R. O. Eades, E. G. Gauntlett, J. P. Litt, J. Mair, G. P. Mills, M.B., W. L. Murphy, L. G. Parsons, F. Scroggie, R. G. Shaw, C. S. Staddon (S.R.), A. L. Urquhart, V. H. Wardle.

Temporary Captains: D. Bird, J. H. Box, C. A. Boyd, St. J. D. Buxton, J. H. Cuthbert, R. S. Dewar, W. H. Fleetwood, S. H. Hay, W. A. L. Henderson, G. B. Holroyde, A. G. Howson, J. F. W. Leech, J. M. Macfie, F. Paine, T. E. Parker.

Temporary Lieutenant J. M. Hammond, D.S.O., M.B. (died of wounds).

Honorary Lieutenants and Quartermasters: P. A. Baynes, T. E. Coggon, M.C., A. T. Hasler, M.C.

Temporary honorary Lieutenant and Quartermaster A. J. Wiseman.

Canadian Army Medical Corps.

Lieut. Colonels: W. B. Hendry, E. J. Williams.

Majors: C. S. McVicar, H. C. Parsons.

Captains: J. E. Campbell, W. A. Clarke, J. G. W. Johnson.

Honorary Captain and Quartermaster H. J. Middleton.

Indian Medical Service.

Major E. Bisset.

FRANCE.

A supplement to the *London Gazette* published on July 23rd contains an additional list of officers, non-commissioned officers, and men recommended for distinguished and gallant conduct and devotion to duty in Sir Douglas Haig's dispatch of April 9th. The following medical officers are included in the list:

Lieut.-Colonel G. H. Goddard, R.A.M.C.

Temporary Captain (acting Lieut.-Colonel) L. D. Shaw, M.B., R.A.M.C.

Captain G. E. Cole, A.A.M.C.

CORRECTIONS.

The following are among the corrections printed in regard to the names of those mentioned in Sir Douglas Haig's dispatch printed in the supplement to the *London Gazette* of May 29th:—*Royal Army Medical Corps*: For temporary Captain J. Davidson, M.B., read Captain J. Davidson, M.B. (S.R.); for Captain G. T. Van Der Vyver, M.B. (S.R.), read Captain G. T. Van der Wyver, M.B. (S.R.).

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Died on Service.

CAPTAIN F. A. DERAVIN, Australian A.M.C.

CAPTAIN IAN MACFARLANE, R.A.M.C.

Captain Ian Macfarlane, R.A.M.C., died at the Military Hospital, Cairo, at July 18th. He was the elder son of the Rev. Norman C. Macfarlane, of Juniper Green, Midlothian, and was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1911. He worked for some time as medical missionary at Nazareth, but had to leave Palestine when Turkey entered the war. He took a temporary commission in the R.A.M.C. as lieutenant on April 14th, 1915, and was promoted to captain after a year's service. He was recently in charge of a military hospital near Gaza.

LIEUTENANT J. E. FOREMAN, R.A.M.C.

Lieutenant John Eugene Foreman, R.A.M.C., was reported as having died on service in the casualty list published on July 21st. He was educated at the London Hospital, took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1906, and, after acting as house-surgeon of the Royal Victoria and West Hants Hospital at Bournemouth, went into practice at West Southbourne. He had only recently taken a temporary commission in the R.A.M.C. and was senior resident medical officer of Boscombe Military Hospital.

Died of Wounds.

LIEUTENANT B. COHEN, R.A.M.C.

A Correction.

In the casualty list published on July 13th the death from wounds of Lieutenant B. Cohen, R.A.M.C., was announced, and it was erroneously assumed that the reference was to Dr. Bertram Cohen of Sidmouth. We regret the error, and are glad to learn that this officer is in good health, and serving on the staff of the Royal Naval Hospital, Plymouth. The officer

who died would appear to be Dr. Benjamin Cohen, formerly of Cape Town, who received his commission as lieutenant in the R.A.M.C. in November, 1916. Dr. Benjamin Cohen was educated at the University of Glasgow and St. Bartholomew's Hospital, and took the degrees of M.B., Ch.B. Glas. in 1913. He was honorary medical registrar at the New Somerset Hospital, Cape Town, and additional medical officer and anaesthetist to the Free Dispensary, Cape Town.

LIEUTENANT J. S. MUNRO, R.A.M.C.

Lieutenant James Sutherland Munro, R.A.M.C., died of gastritis at the Officers' Hospital, Baghdad, on July 16th. He was the youngest son of Mr. Munro, of Dornoch, Sutherlandshire, and was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1900. He had only recently taken a temporary commission in the R.A.M.C., having previously been in practice at Pendleton, Manchester.

Wounded.

Captain J. G. A. Campbell, Canadian A.M.C.

Captain W. E. David, M.C., R.A.M.C. (temporary).

Captain G. D. Eccles, R.A.M.C. (temporary).

Captain A. T. Hawes, R.A.M.C. (temporary).

Captain E. H. Helby, R.A.M.C. (temporary).

Captain F. G. McNaughten, R.A.M.C. (temporary).

Captain G. M. Miller, R.A.M.C. (temporary).

Captain E. M. B. Payne, R.A.M.C. (temporary).

Captain C. P. Rosenthal, Australian A.M.C.

Captain and Quartermaster A. Morrison, R.A.M.C.

Captain H. D. Smart, M.C., R.A.M.C. (temporary).

Lieutenant F. Corner, R.A.M.C. (temporary).

Sister R. Pratt, Australian Nursing Service.

Wounded and Missing.

Captain H. K. Ward, M.C., R.A.M.C. (S.R.).

Erroneously Reported Wounded.

Captain E. A. Walker, R.A.M.C. (temporary), previously reported as wounded (*BRITISH MEDICAL JOURNAL*, July 14th) was reported as *not* wounded in the casualty list published on July 19th.

DEATHS AMONG SONS OF MEDICAL MEN.

Cooke, Christopher A. G., Midshipman R.N., eldest son of Lieut.-Colonel A. Cooke, R.A.M.C. (T.F.), of Cambridge, killed in the blowing up of H.M.S. *Vanguard* on July 9th. He was born in 1899, entered Osborne in 1912, and was mobilized at the end of his first term at Dartmouth. He was serving on H.M.S. *Aboukir* when she was torpedoed on September 22nd, 1914, and on H.M.S. *Vanguard* in the battle of Jutland on May 31st, 1916.

De Segundo, William, Midshipman R.N., second son of Major C. S. de Segundo, R.A.M.C. (T.F.), killed in the blowing up of H.M.S. *Vanguard* on July 9th, aged 17.

Duke, Alan C. H., Lieutenant Commander R.N., eldest son of the late Colonel A. W. Duke, R.A.M.C., died on July 11th, of injuries received in the blowing up of H.M.S. *Vanguard* on July 9th.

Garlike, George Popham, Somerset Light Infantry, second son of the late Dr. Garlike of Sutton Benger, Wiltshire, died in hospital abroad on July 5th, aged 35.

Green, Charles Arthur, M.C., Second Lieutenant Royal Garrison Artillery, son of the late Dr. Arthur Green of Gateshead, killed on July 13th, aged 20.

Robertson, James, Second Lieutenant Highland Light Infantry, son of the late Dr. James John Robertson of Oakfield, Montgomery, Wales, died of wounds on July 9th, aged 19. He was educated at Merchiston, where he was in the O.T.C., and had begun to work as a farming pupil, when he took a commission in November, 1916.

Woodforde, Hector Sidney Ridout, Australian Imperial Force, fourth son of William Sidney Ridout Woodforde of Goondiwindi, Queensland, killed February 25th, 1917.

Woodforde, Philip Sidney Scane, Major Australian Imperial Force, eldest son of the late Alfred Ernest Woodforde, L.R.C.P., of Uralla, New South Wales, died of wounds on May 6th. He was a first cousin of Hector Woodforde, both being grandsons of the late Dr. W. T. G. Woodforde, of Spencer's Wood, Reading.

Ziani-de-Ferranti, Basil, M.C., Major Royal Garrison Artillery, eldest son of Dr. S. Ziani-de-Ferranti, of the Hall, Baslow, Derbyshire, died of wounds on July 12th.

MEDICAL STUDENT.

Drewe, Adrian, Major Royal Garrison Artillery, killed on July 12th. He was the eldest son of Mr. J. C. Drewe, of Wadhurst Hall, Sussex, and was educated at Eton, at Trinity College, Cambridge, where he graduated as B.A., with first-class honours in psychology, and had passed his first and second M.B., and at St. Bartholomew's Hospital. He was a well known rowing man at Eton and at Cambridge, where he rowed three years in the third Trinity light four, which was then head

of the river, and won the University trial pairs in 1913. He got a commission in the R.G.A. on November 2nd, 1914, and went to the front in the spring of 1915.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

NOTES.

INVESTITURE.

At the investiture by the King at Buckingham Palace on July 21st the recipients were in two categories—the men themselves who had won distinction, and the near relatives of those who had died. In the latter category, unfortunately, occurred the name of Lieutenant Donald Mackintosh, Seaforth Highlanders, who won the Victoria Cross by an act of heroism recorded in our issue of June 23rd, but which cost him his life. The cross was received by his parents, Dr. Donald Mackintosh, C.B., medical superintendent of the Western Infirmary, Glasgow, and Mrs. Mackintosh.

Ireland.

IRISH COUNTIES WAR HOSPITAL.

The Irish Counties War Hospital was formally opened on July 18th by Lady Wimborne. Her Excellency said that the hospital was the crystallization of a desire on the part of the counties of Ireland to provide by their own efforts and by their own self-sacrifice some means of relief and help for wounded soldiers. The idea had originated with some of the directors of the county Red Cross organizations, who desired local institutions for their wounded. But it had been pointed out to them that a central hospital in County Dublin would be really more productive of good, and it was creditable to those organizations that they had at once sunk their individual feelings and thrown themselves so heartily and completely into the organization of a great central hospital, where the biggest and best results might be had for the money that had been subscribed. The building, so well situated, in such good air, was going to be a real help to the brave Irishmen who would be there. Of the many supporters and founders of the institution, she mentioned Mr. Hely, to whose efforts on behalf of the hospital were due so many generous subscribers, and Dr. Lumsden who, in his capacity as head of the V.A.D.'s, had done most wonderful work in connexion with it.

CRAIGAVON NEURASTHENIC HOSPITAL FOR SOLDIERS, BELFAST.

Lieut.-Colonel James Craig, M.P., and Mrs. Craig have lent their large house and grounds to the Ulster Volunteer Force Hospital Board of Management to be used as a hospital for discharged soldiers and sailors suffering from neurasthenic shell shock and kindred affections. The house is situated on the rising ground of the Castlereagh Hills, on the south side of Belfast Lough, and commands a view of the lough and much of the adjoining beautiful and wooded country; it is about three to four miles from the city. The grounds are over 30 acres, and the owner has also given permission to make all necessary alterations. The committee has arranged to erect a temporary ward in line with the loggia and large billiard room, and it is expected that the hospital will ultimately accommodate 100 patients. There will be numerous one-bedded rooms and small wards. The kitchen is enlarged, and a large dining-room is being built adjoining. The billiard room is for the present to be used as a ward, but in the near future it will be converted into a recreation room for concerts, lectures, and through the day for reading, etc. There will be a nursing staff of one matron, three sisters, and about twelve V.A.D. nurses, and accommodation for them is being provided upstairs. The Board of Management of the Ulster Volunteer Force Hospitals have appointed Dr. H. L. McKisack medical officer in charge, and he and Dr. W. Calwell and Dr. R. W. Leslie will form the visiting staff. Dr. J. Adamson, lately house-physician in the Royal Victoria Hospital, Belfast, is the resident medical officer and superintendent.

The opening ceremony was performed on July 21st in the beautiful grounds in front of the house. The Lord Mayor of Belfast occupied the chair, and called upon Mrs. James Craig, who declared the hospital open, and handed it over to Sir Edward Carson for the Ulster Volunteer

Force Hospital Board. Sir Edward moved a hearty vote of thanks to the donors for their magnificent gift. The Right Hon. G. N. Barnes, Minister for Pensions, in seconding the vote of thanks, said the country must not be content with giving a man a pension; it must build him up and return him a self-supporting and self-respecting unit to the community.

Sir Arthur Griffith-Boscawen moved a vote of thanks to the Lord Mayor for presiding, and expressed his pleasure at being present and his high appreciation of the gift. This was seconded by Mr. R. V. Williams, Chairman of the Belfast Branch of the War Pensions Committee. This is the second war neurasthenic hospital to be opened, and the sixth war hospital which this energetic board has established and is working. It follows on the lines of Golders Green, London, and will be under the guidance of Lieut.-Colonel Sir John Collie, director of neurasthenic institutes.

Scotland.

REPORT OF THE CENTRAL MIDWIVES BOARD FOR SCOTLAND.

The appearance of the report on the work done by the Central Midwives Board for Scotland for the year ended March 31st, 1917, shows that the Midwives (Scotland) Act, which was passed on December 23rd, 1915, is now in operation. The Board was constituted in February, 1916, but, until the two members to be selected from the midwives on the roll could be added, it was not of full size; consequently the final revision of the rules was delayed until after May 25th, when the representative midwives were present. Meanwhile the new rules prepared by the Central Midwives Board for England had become available, and the Scottish Board resolved that the curriculum, etc., prescribed should be coextensive with their requirements. The rules received the approval of the Privy Council on August 26th. Other matters which were attended to during the year were largely of the nature of adjustment and reciprocal recognition regarding curriculum and examination between the two boards. In the meantime, however, reciprocal recognition of examinations is incomplete, for midwives passing an examination in Scotland cannot be enrolled in England without passing also the examination of the English Board. The first examination of the Scottish Board was held in October, 1916, when seventy-seven candidates entered, of whom sixty-nine passed; the examination was conducted simultaneously at Edinburgh, Glasgow, Dundee, and Aberdeen. For the period to March 31st, 1917, the number of midwives enrolled was 2,026, including the sixty-nine above mentioned by examination. To the report, which is signed by Sir Halliday Croom, chairman, and D. L. Eadie, secretary, there are appended lists of teaching institutions and teachers recognized, of certified midwives approved to sign certificates, and of the examiners. The institutions are the Royal Maternity Hospitals in Edinburgh and Glasgow, the Maternity Hospitals in Aberdeen and Dundee, the Hospice of the Edinburgh Hospital for Women, the Queen Victoria Jubilee Institute, and the Church of Scotland Deaconess Hospital, Edinburgh; the Nurses Training Home, Govan, and the Glasgow Eastern (Poor Law) Hospital, Glasgow.

PUBLIC HEALTH OF EDINBURGH.

The annual report of the public health department of the City of Edinburgh for 1916, whilst much smaller than in the pre-war years, contains a great many facts and figures of outstanding importance. Dr. Maxwell Williamson, too, continues to make his statistics interesting. A remarkable sign of the times is the prominent position given to the birth-rate; it is actually more important than the death-rate. Thus, whilst the natural increase in the population of Edinburgh—that is to say, the excess of births over deaths for 1916 is 936, as compared with 432 in 1915—that greater increase is not due to a rise in the number of births but to a fall in the number of deaths, and, as a matter of fact, to the comparative freedom of the city from measles and whooping-cough. Indeed, the birth-rate has fallen—from 17.8 in 1915 to 17.4 in 1916, a figure, says Dr. Williamson, which is the lowest yet recorded; and he adds:

It is to be kept in mind regarding the low birth-rates which are now ruling that these do not mark a specially sudden fall in

consequence of war conditions as might at first sight be expected. No doubt these conditions have an important bearing on the birth-rates, but along with this statement there must be taken the other fact, that the diminution in the rates during the war has not been disproportionate to the diminishing rates which have ruled for wellnigh half a century. Thus, in 1871, the rate was 34 per 1,000; in 1884, 30; in 1888, 29; in 1890, 27; in 1894, 26; in 1902, 24; in 1905, 23; in 1911, 20; in 1913, 19; and then the two succeeding war years—1915 the rate was 17.8, and in 1916, 17.4.

The decrease, therefore, has not been much exaggerated during the three war years. Perhaps the serious nature of the effect of the falling birth-rate is more clearly shown by a table in the report exhibiting the increase in the population since 1861. It is only necessary to look at the figures for the terminal years (1861 and 1916) to understand why there is ground for anxiety. In 1861 the population was 170,444 and the births (with a rate of 33.4 per 1,000) were 5,694; in 1916 the population was 330,905 and the births (with a rate of 17.4) were 5,748. In other words, whilst the population had almost doubled, the total number of births had only increased by 54. At the old rate prevailing in 1861, there would have been about 11,000 births in 1916. No wonder Dr. Williamson has ceased since 1914 to put into his table the number of years which will be required to pass before the present population of Edinburgh is doubled, and it is not surprising that a large part of the present report is occupied with the forecast of the child welfare scheme which has during the past few weeks begun to operate, in part at least, in the city. The "torrent of babies" of which Tennyson the poet spoke in apprehensive terms some forty years ago, has ceased, in Edinburgh at any rate, to threaten the civic landscape. The cancer death-rate, 1.3 per 1,000, remains the same in 1916 as it was in 1915, and the same holds of the phthisis death-rate, 1.1 per 1,000; the fall of the infectious diseases death-rate from 1.5 per 1,000 in 1915 to 0.6 per 1,000 in 1916, and in the infantile mortality from 132 per 1,000 births in 1915 to 100 per 1,000 in 1916 are matters for rejoicing. In 1915 there were 774 deaths under one year, whilst in 1916 there were only 575; but the marked reduction has been almost entirely explicable by the fall in the zymotic rate, which reached an exceptionally low level. There therefore remains plenty of scope for the beneficent action of the child welfare scheme in preparation, and the same remark applies to the scheme in preparation under the Venereal Disease Order, which Dr. Williamson hopes to see in action before long. Unfortunately (as he points out) the order contains no compulsory power, and even after a scheme has been framed and put into force persons suffering from venereal disease in an actively communicable form may still remain at large in the streets unless they choose to take advantage of the treatment which will be provided for them. There are many other matters of interest in the report, including the rather ominous, although slight, increase in the density of the population.

England and Wales.

THE MEDICAL TRAINING OF WOMEN IN WALES.

IN connexion with the recent collegiate gathering at Bangor the annual meeting of the general committee for the promotion of the medical training of women in Wales was held in the Council Chamber of the University College, Mr. D. Ll. Thomas, chairman of the Executive Committee, presiding. The movement was started and a general committee appointed at a meeting held at Cardiff in February, 1916, the object being to facilitate the entrance of women into the medical profession. Owing to war conditions increasing the demand for medical service, the losses sustained amongst doctors serving abroad, and the depletion of medical students due to military service, the need for the training of women has, in the opinion of the committee, become urgent. The chairman pointed out that although the medical school was situated at Cardiff and the training would be given there, the organization was intended to serve the whole of Wales and to assist students from all parts of Wales. The Hon. Violet Douglas-Pennant, one of the National Insurance Commissioners for Wales, said that the movement aimed at

turning out such women as had rendered splendid service during this war in Serbia, Salonica, and other places. From a practical point of view she hoped that grants in aid would not be given till the fourth year of studentship, and that they would not be given at all except in absolutely justifiable cases. Principal Griffiths, of the University College, Cardiff, referring to the examination lists of the women candidates for the medical profession who entered at the beginning of last session, regretted to say that the results were quite deplorable. The fact was that they were asking too much of these young women until they were better prepared at the schools. They were expected to pass their first examination at the end of their first year. Practically none of them had done it. He was afraid that a great number of the students would not pass in the second year either, and that proved the wisdom of Miss Douglas-Pennant's suggestion that grants should not be awarded till the students had proved themselves capable. He suggested that those who had to do with the secondary school education of women students should give serious attention to the matter and try to get their science teaching to a higher level all round, and not specialize merely in botany. Principal Reichel (Bangor) also approved Miss Douglas-Pennant's suggestion, and dwelt on the usefulness of a loan fund for students.

HEALTH OF LANCASHIRE.

According to the quarterly report of the M.O.H. for the county of Lancashire for the quarter ending March 25th, it appears that there was a considerable increase in the general death-rate as compared with the same quarter last year. The rate in the urban districts had risen from 13.2 per 1,000 to 14.7, and in the rural districts from 12.9 to 15.8. The total deaths from all causes were 6,052; of these, 258 were due to epidemic diseases, excluding diarrhoea, 456 to tuberculosis, and 1,692 to bronchitis and pneumonia. The figures for measles are especially high; there were during the quarter 7,485 cases with 122 deaths, as compared with 5,188 cases and 60 deaths in the same quarter last year. Negotiations are still proceeding with the various hospital authorities in the county with regard to the treatment of venereal disease, and apparently the scheme is not yet complete. For maternity and child welfare work four county health visitors were appointed in April. They have already commenced their duties, and will report monthly on their respective districts.

The Midwives Act Committee reports that the number of midwives on the list was 776, but only 649 were actually in practice. Exactly half the total number are on the list because they were in bona-fide practice in 1901. The records of sending for medical aid numbered 636, and 96 stillbirths were reported. As in previous quarters, by far the largest number of cases where medical aid was called in were for ruptured perineum or tedious labour, while in the infants inflammation of the eyes accounted for most of the cases. No fewer than 90 cases of ophthalmia neonatorum were reported from all sources, and in connexion with them eight charges of negligence were preferred against midwives. The cases of puerperal fever numbered 15 with 3 deaths, as compared with 21 cases and 6 deaths in the previous quarter, and in connexion with them there were two charges of neglect against midwives. At the request of the Local Government Board a return was prepared showing the supply of midwives in each rural parish, and the Board urged the county council to frame a scheme for establishing a trained midwife in areas which at present are in need of such service, the Board's grant for maternity and child welfare work being available in respect of the necessary expenditure.

It was recently stated in an American newspaper that Dr. Yamei Kin is the only Chinese woman graduate of an American medical college. This statement is said to be inaccurate. According to the *New York Medical Record* Dr. Mary Stone (Meigil Shie), who is in charge of a hospital at Kiukiang, where she treats about 25,000 patients a year, graduated at the University of Michigan in 1896. Dr. Ida Kahn, said to be a direct descendant of Confucius, who is now head of a hospital at Nan-Chang where 23,000 patients are treated annually, graduated in the same class. Dr. Hu King Eng, head of the Woolston Memorial Hospital, Foo Choo, graduated at the Women's Medical College, Philadelphia, in 1894. Dr. Li Bi Cu of Ngan-Si en graduated at the same institution in 1906.

Correspondence.

THE BASLE ANATOMICAL NOMENCLATURE (B.N.A.).

SIR.—Any one who surveys the chaos which has come over the naming of the parts of the human body in recent years must be moved to exclaim with the ancient Hebrew: "Cursed be he that removeth his neighbour's landmarks." Perhaps another quotation is even more apt for the present circumstances: "Some remove the landmarks; . . . behold as wild asses in the desert go they forth." With your permission I want to examine this "wild ass" movement in a branch of knowledge which concerns every medical man; to trace its origin and aims, and to see how far it is possible for a well-intentioned but wrong-headed movement to be converted into one which will yield a real and lasting benefit to human anatomy.

In the late Eighties of last century leading German anatomists realized that a great advantage would ensue if a uniform system of anatomical nomenclature were introduced to German medical schools. In 1889 a commission was appointed by the Anatomische Gesellschaft. After six years of effective labour the commission submitted to the German Anatomical Society, when it met in Basle in the early summer of 1895, a new nomenclature, which was adopted by the society and named the B.N.A.—*Basle Nomina Anatomica*. The members of the society received it without demur; it was primarily intended to secure uniformity in German schools; there was no intention of dictating to the rest of the world. But I am quite certain if the leaders in France, Italy, Britain, or America had submitted such a list to their respective societies it would not have been accepted in faith: the members of those societies would have insisted on the rights of free men—of criticism and of choice. That is the first point we have to remember. The nomenclature (B.N.A.) which is now being pressed on us was designed not for us but for the needs of German schools.

The German system has merits; there could not be anything more stupid than to deny ourselves the privilege of improvements because at the present time the people amongst whom these improvements originated are our enemies. One outstanding merit, to my way of thinking, was that all the proper names which cumbered the pages of our textbooks got notice to quit. Sylvius, Fallopius, Eustachius, Poupart, Gimberaat, Wrisberg, Wirsung, Gasserius, Wharton, Hunter, Monro, Peyer, Treitz, Santorini, Magendie, and all their colleagues, ancient and modern, had to retire to their proper places—the dusty pages of historical records. New names had to be coined to take their places, and the German genius is clumsy when applied to the art of nomenclature. It would have been otherwise if the task had fallen to our colleagues of France—they have a gift for names. A very great number of the new terms proposed are clumsy and inapt. Eustachius had to go, but why call his tube "tuba auditiva"? it is the tube of the tympanic cavity—the tympanic tube. The pharynx is a big and important part, and when we read of the "canalis pharyngeus" we expect an important structure, and not the minute and relatively unimportant old friend—the pterygo-palatine canal. The foramen of Magendie becomes the "apertura medialis ventriculi quarti"; Pacchionian bodies, "granulationes arachnoidales"; the foramen of Winslow, "foramen epiploicum," while the pouch of Douglas becomes the "excavatio recto-uterina." Many of our terms become curiously twisted in the German system: acromio-thoracic, big and clumsy enough, becomes more clumsy in the B.N.A. form, "thoracico-acromialis"; palato-glossal becomes "glosso-palatine," and palato-pharyngeal "pharyngo-palatine." There were not a few pedantries introduced. "Hilus" was intended to replace our hilum; "capitulum," capitellum; "annularis," orbicularis. Although anatomists of other countries used "malar" as the designation for cheek bone, the German term "os zygomaticum" was retained in the B.N.A. The insignificant joint between the arytenoid and corniculate cartilages received the high-sounding designation of "synchondrosis arycorniculata," while the inferior tibio-fibular articulation became the "tibio-fibular syndesmosis." It is said that the German anatomists, in drawing up the

B.N.A., gave full consideration to the names used by anatomists in other countries. However that may be, they preferred to retain their own term for the second cervical vertebra, "epistropheus," while trapezium and trapezoid of the carpus became "os multangulum majus" and "os multangulum minus." In short the B.N.A. was founded on the usage in German schools, and no attempt was made to bring the new nomenclature into harmony with the usages in France, Italy, Russia, or English-speaking countries.

How does it come about that a scheme of names, compiled under the circumstances just narrated, is being forced on English-speaking medical men? To obtain an insight to the commencement of the movement we must turn to the introduction which Professor Lewellys F. Barker, Sir William Osler's successor in the Chair of Medicine at Johns Hopkins University, wrote to a work which he published in 1907, and entitled *Anatomical Terminology*.

"Now that the B.N.A. is being followed in medical and scientific schools throughout the world," he wrote, "and has been adopted as the language used in several newer English and American anatomical textbooks and atlases, it has occurred to the publishers of Morris's *Anatomy* that a concise statement concerning the origin and exact nature of this list of anatomical terms would be interesting and helpful to anatomists, physiologists, biologists, pathologists, and clinicians." Now I can assert without fear of contradiction that, in the year 1907, there was not a single anatomical school or teaching hospital throughout the whole length and breadth of Great Britain and Ireland in which the B.N.A. had been adopted; there was not a school in which there was any wish to adopt the new nomenclature *en bloc*. But it did occur to the publishers of an excellent and deservedly successful textbook on anatomy to adopt the new nomenclature. What have publishers to do with the terminologies to be used by medical men? Publishers make commercial adventures, and in making such adventures we cannot blame them if they exploit, as milliners do, the calls of fashion. If the new fashion "catches on" old wares go out of date and become unsaleable. It was under the aegis of publishers that the German terminology—which we politely name the B.N.A.—was introduced to English-speaking schools. There always has been, and always will be, in every class a very considerable section which is susceptible to fashion, and mistakes movement in a circle for real progress. It is that section which has capitulated to the new nomenclature—as the publishing trade hoped it would.

The picture which Professor Barker drew of the state of anatomical terminology in 1907 was, in my opinion, not a little exaggerated. "These double and multiple terms were passed on from lecture to lecture and from textbook to textbook, and as a result of this anarchy in the creation and use of terms the weight became terribly grievous. Teachers and pupils writhed under it." I was under the impression that the conditions pictured by Professor Barker referred to the state of matters in America rather than in England, but in that I seem to be mistaken, for in his introduction to *The Basle Nomenclature*¹ Dr. E. B. Jamieson, Lecturer on Anatomy, University of Edinburgh, repeats Professor Barker's arguments and figures. It is strange that when Professor Barker was drawing a picture of anarchy I and the men with whom I was then associated were unconscious of it. In examinations of the Conjoint Board, and in those for the Fellowship of the English College, and at examinations in provincial universities, we never met with any evidence of this anarchy. Teachers and taught from different universities found themselves with a common system of names. I cannot remember a single meeting of British anatomists where any difficulty or ambiguity was caused by a difference in the use of terms. But that state of matters has passed; now there is anarchy and chaos. The student's work has indeed become grievous, all because a few well-intentioned but stupid people yoked our English wagon to the German chariot. They were to give us a millennium; instead they have given us pandemonium.

In this country we had reached an approximate state of uniformity as regards the use of anatomical terms—as near the ideal as we are ever likely to attain. No one regarded the nomenclature as an ideal one, but it was

¹ *The Basle Nomenclature*. By Dr. E. B. Jamieson. W. Green and Son. 1915.

believed to be worth while to submit to its imperfections in order to retain uniformity. But now that uniformity is gone the time has come for every medical man, be he teacher or pupil, to use his best judgement at the present juncture of affairs. Three courses are open to us: (1) To accept the B.N.A., with all its defects, as the standard English nomenclature; that course will not be adopted in either France or Italy. (2) To retain our present nomenclature, with all its disadvantages. It is based on the system which prevails in France and Italy. (3) To accept such terms from the B.N.A. as are manifestly more apt than those we now employ. It is the third course which I would press now on the attention of medical men. Its advocates speak of the B.N.A. as if it were a decalogue to be obeyed in its entirety; it never seems to have occurred to either Professor Barker or Dr. Jamieson that it was possible to accept the good and leave the bad. That, however, is what one hopes may happen in every country where science rests on a democratic basis. Meantime, there will be a period of chaos, out of which the fittest names will ultimately survive. Medical men must insist on a freedom of choice. At the very least we must keep in mind and be influenced by the usages and needs of France, Italy, America, Russia, Holland, Denmark, Norway and Sweden, as well as by those of Germany and Austria.

I do not propose now to enter into an analysis of the merits and demerits of the Basle nomenclature. All that I would request in the meantime is that medical men should remember that English-speaking anatomists are heirs to a goodly heritage; in no country has anatomy been exploited by the practical man more than in our country, and our nomenclature has been shaped for our practical needs more than in Germany. My aim is gained if I have made physicians and surgeons realize the nature of the movement which threatens to overwhelm the system which they learnt in their college days. They must not think, when students and young medical men speak to them of the internal lateral as the tibial collateral ligament of the knee-joint, or the internal lateral as the ulnar collateral of the elbow-joint, or the auricle of the heart as the atrium, or the base of the bladder as its fundus, that they themselves are out of date; they should regret that such a student should be suffering for the wrong-headed zeal of teachers who are willing to sacrifice the living spirit of English anatomy for the Dead Sea fruit of a foreign terminology.—I am, etc.,

ARTHUR KEITH.

ARMY MEDICAL ECONOMIES.

SIR,—Your article on army medical economies (July 14th, p. 52) classifies regimental medical officers among the partly employed—often underworked, but not always. There are, however, in every division three regimental M.O.'s who never go near any fighting and never do a full day's work. These are the M.O.'s of the divisional train, the divisional ammunition column, and the divisional engineers.

The divisional train carries supplies and forage from railroad to deliver them to quartermasters of units. As wagons go up in twos and threes to different parts of the line it may occasionally happen that a man gets hit. During the best part of a year that I have been M.O. of a train this has happened once. The man went to the nearest advanced dressing station, and was evacuated to the base before I heard of his being wounded. In the same way as the train carries supplies the ammunition column carries ammunition. The doctor of the unit is the last person likely to be called in in the case of one of his men being wounded. The case of the R.E. is different. They do go into the line and suffer casualties, but when they do so they are attached to infantry and attended by infantry doctors.

I suggest, therefore, that three doctors per division could be saved by abolishing these underworked appointments. The work could be done in one of two ways—either the train or the engineers as a whole could be looked after by a doctor who did some other work as well, or else each A.S.C. company or field company R.E. could be treated as a unit of the brigade which it serves, and would be attended by one of the infantry doctors, as is now done with machine-gun companies and trench mortar batteries.—I am, etc.,

July 21st.

TRAIN M.O.

PAYMENT OF MEDICAL OFFICERS TO V.A.D. HOSPITALS.

SIR,—I do not agree with Dr. Mothersole that "few, if any, of the medical officers concerned would wish to receive any payment for their services." The cost of living for medical men, as for other members of the community, has risen some 40 per cent., and the incomes of many have fallen considerably since the war began. Patients, both private and insured, have joined up in large numbers, and many private patients of both sexes have become employed, and therefore insured, persons. The War Office has announced that medical officers to auxiliary war hospitals are entitled to payment, which is made by the War Office and not by any charitable body. By all means let those men who can afford to do without the money devote it as suggested by Dr. Mothersole, but let every man ask for the payment to which he is entitled.—I am, etc.,

Northampton, July 24th.

A. W. COOKE.

QUO VADIS?

SIR,—In your issue of July 14th Dr. Rawdon Wood proceeds, with very soft tools, to "nail to the counter" Dr. Fordyce's statement that in 1912 the Government had ready a whole-time service scheme, and was prepared to work it. This is described by Dr. Wood as "a bluff pure and simple." It was very far from being so, *pace* Dr. Wood, but the proof which I might cite, communicated *in camera*, cannot be stated here. But I can assure Dr. Wood that at the final meeting of the practitioners of this district, before the Insurance Act came into being, this proof was given convincingly by one to whom the profession owes a deep debt of gratitude for his unselfish and unwearying labours on their behalf in those stormy months, and whose evidence, were I but allowed to name him, would be received as final and irrefutable. At this meeting Dr. Fordyce presided. The evidence, if produced, would sufficiently dispose of Dr. Wood's "proof" to the contrary.

I may perhaps add that, when seeing a prominent official under the Act shortly after this, I was told: "If there had been trouble, I don't say we should have staffed the country districts, but there would have been no difficulty about the town"—meaning Cambridge. After hearing the evidence referred to, I had no difficulty in accepting the statement.—I am, etc.,

Histon, Cambridge, July 21st.

L. GWILLIN DAVIES.

MEDICAL STUDENTS IN AND OUT OF THE RANKS.

SIR,—I read in this week's issue that Professor Littlejohn of Edinburgh "knows of several senior students who are anxious to do hospital work or help in practices during the summer vacation." Three years ago, when the war began, these men would be junior students, would they not? If so, how, then, does it happen they have escaped military service? It would seem from what one hears quite a number of medical students have done so (vide a letter in the last issue of the BRITISH MEDICAL JOURNAL signed by "J. A. A.").

Those of us who have medical student sons fighting may well ask with him "whether patriotism really pays."—I am, etc.,

Felton, July 21st.

ROBERT A. WELSH.

A TOO-PUNGENT MOUTH-WASH.

SIR,—Mr. J. T. Hall is right, I think, in pointing out at this time of year that a saturated solution of thymol is somewhat strong for a mouth-wash. The fact is that with a substance such as thymol, the solubility of which rises with the temperature, a saturated solution in ordinary tap water is necessarily much stronger during the summer than in the winter, when I tested it. The antiseptic power increases rapidly with concentration and temperature, so that the solution may well be diluted, as I suggested in the article referred to, "should it be found to be irritating." Certainly no one should, and I can hardly imagine would, persist in the use of anything found to be irritating; unfortunately, most antiseptics tend to be so, if strong enough to be effective germicides. Thymol is by no means ideal, but when used in solutions of suitable strength it is

better than anything of which I know for preventing the growth of the tartar organisms.

Upon what evidence, I wonder, does Mr. Hail base his conclusion that a large proportion of the many cases of gingivitis and pyorrhoea are "due entirely to the prevalent use of mordant mouth-washes and pastes." Surely these diseases existed long before man thought of anything so hygienic as a mouth-wash!—I am, etc.,

Oxford, July 22nd.

HELEN GOODRICH.

The Services.

AUXILIARY ROYAL ARMY MEDICAL CORPS FUND.

THE following donations for the Officers' Benevolent Branch have been received during the quarter ending June 30th:

Sum of £42 4s.—Officers' Training Centre, Birt.

Sum of £10 10s.—Dr. Stephen J. Henry.

Sums of £5 5s.—Major T. H. Ray, Captains E. D. Pineo, H. Richmond.

Sum of £5.—Captain K. Macewen.

EXCHANGE.

MEDICAL OFFICER in Charge Base Dépôt requires exchange with medical officer of F.A., M.A.C., or R.E.—Address No. 2450, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Universities and Colleges.

UNIVERSITY OF WALES.

HONORARY DEGREES.

AT the annual collegiate meeting of the Court of the University of Wales, held at the University College, Bangor, on July 18th, in addition to the ordinary admissions of successful graduates, honorary degrees were conferred upon a number of persons who have rendered distinguished service to the principality and to the empire. Lord Kenyon, who occupies the position of Senior Deputy Chancellor for His Majesty the King, presided over the Congregation of the University. Owing to the absence of the large majority of the men students, who are engaged in the war, the ceremony was shorn of some of its usual vivacity, but the proceedings throughout were most impressive, and the women students strove hard to give spirit to the "college war cries" which help to enliven such occasions.

Degrees voted to the Right Hon. Wm. Abraham (Mabon, the miners' leader); to the Rev. J. Williams (Pedrog), one of the Welsh Chaired Bards; M. Henri Gaidoz, the learned editor of the *Revue Celtique*; and Sir W. Goscombe John, R.A., the eminent sculptor, were not conferred owing to the absence of the recipients, but the other honours announced were warmly welcomed and tumultuously applauded. The degree of M.A. was conferred on the Rev. Thomas Shankland for services rendered to Welsh history and bibliography; that of M.Sc. on Mr. D. Cledlyn Evans for researches into the geology of West Wales; that of D.D. on Colonel the Rev. John Williams, Brynecyn, for distinction as a Welsh preacher; that of D.Sc. on Colonel Sir Robert Jones, F.R.C.S., C.B., for eminence in science and in the practice of orthopaedic surgery; and that of LL.D. on Lieutenant-General Sir James Hills Johnes, V.C., G.C.B., for services rendered to the country as a soldier and to the University as its Treasurer. He was a life-long friend and companion of the late Lord Roberts, and has for many years been one of the popular figures of Welsh national life; his presentation to the Vice-Chancellor, as "a soldier, administrator, and educationist," by Principal Sir Harry Reichel, evoked most hearty enthusiasm. Equally cordial and equally sincere was the welcome accorded to his younger "brother in honours" Colonel Sir Robert Jones. In presenting him, Professor Reginald W. Phillips, M.A., D.Sc., of the Bangor University College, said that, though orthopaedics taken literally was the branch of surgery concerned with the cure of deformities in children, the term by usage had been so extended that it now covered cases of deformity in persons of mature years. While in the past Sir Robert Jones's beneficent work had lain largely among children, latterly he had devoted himself almost exclusively to the cure of soldiers who had returned broken and maimed from the battlefield. More than any other man he had created orthopaedics in these islands as a recognized special branch of surgery, and his pre-eminent position was acknowledged by his medical colleagues everywhere throughout the civilized world. It was a delicate compliment to him that the orthopaedic surgeons of the recent American contingent had voluntarily placed themselves at his orders and under his command. The university was proud to hail Sir Robert Jones as a great Welsh orthopaedic surgeon, but he would himself be the first to acknowledge that he was carrying out and carrying forward the great principles of orthopaedics laid down by that remarkable Anglesey Welshman, Hugh Owen Thomas of Liverpool, whose skill in orthopaedic surgery was little short of genius. Early this year the King had invested Colonel Robert Jones with the military C.B., and at the King's birthday he received the honour of knighthood. The knights of old were required by their oaths never to draw sword save in a good cause. What

worthier cause could any knight of the most glorious days of chivalry have inscribed on his banner than that of the paralysed child and the crippled soldier? Professor Phillips, then addressing the Vice-Chancellor, said:

DOMINE VICE-CANCELLARIE: Virum illustrissimum, equitem spectabilissimum qui artem chirurgicam quasi patrimonio acceptam ingenio et labore suo ad summum perduxit secretum corporis humani compagem perspexit truncatos militum artus magica quadam solertia recoxit, praesento tibi ad gradum Doctoris in Scientia admittatur ROBERTUS JONES.

Sir Robert Jones's name is a household word throughout North Wales, and Professor Phillips's just tribute was thoroughly appreciated; seldom, if ever, has the bestowal of a degree by the University of Wales been more heartily welcomed. Since the inception of the University the degree of D.Sc. has been conferred only upon Sir John Williams, Bt., G.C.V.O., Dr. Frederick Roberts (Emeritus Professor of Medicine, University College, London), Sir William H. Preece, K.C.B., and Professor Galloway, F.G.S.

UNIVERSITY OF LONDON.

THE following candidates have been approved at the examinations indicated:

M.D.—Branch I (Medicine): Mirza Mohammed Khan, Helen M. M. Mackay, D. J. Munro, Margaret R. Paterson.

Branch IV (Midwifery and Diseases of Women): Charlotte L. Houlton, Hilda M. Scarborough.

M.S.—Branch I (Surgery): C. Banting.

LONDON HOSPITAL MEDICAL COLLEGE.

The following awards have been made: Price and Entrance Scholarships in Science, (1) £100, R. A. Madgwick, (2) £50, D. Hunter; Buxton Entrance Scholarship in Arts, £31 10s., C. F. Fenton; Prize in Clinical Surgery, £20, G. Adler and H. Gluckman (aeq., prize divided); Prize in Clinical Obstetrics and Gynaecology, £20, F. W. A. Watt; Duckworth Nelson Prize in Practical Medicine and Surgery, £10, D. J. Valentine; Sutton Prize in Pathology, £20, I. H. Zortman; Wynne Baxter Prize in Forensic Medicine, £5 5s., G. R. Woodhead; Anderson Prizes in Elementary Clinical Medicine, value £3 each, A. E. Clark-Kennedy and M. Marcus; Honorary Certificates, D. Wallace, J. M. Winnett, and I. J. Cruchley; Prizes in Elementary Clinical Surgery, value £5 each, J. C. Collins, J. Brodetsky, I. J. Cruchley, and A. Eidinow (aeq., prize divided), and M. W. B. Bulman; Prize in Minor Surgery, £5, F. H. W. Tozer; Honorary Certificates, D. Hunter and D. R. Thompson; Prize in Anatomy and Physiology, value £25, M. Marcus; Prize in Practical Anatomy, value £6, E. L. Sergeant; Honorary Certificates in Inorganic Chemistry, M. Remy and F. C. Hunt.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.

The following awards have been made:—Burney Yeo Scholarships: E. H. Culver, M. S. Thomson. Senior Scholarship: L. B. Goldschmidt. Tanner Prize divided between D. C. Clark and C. K. Scates. Todd Prize and Medal: A. Blackstock. Class Prizes: (Medicine), L. M. Moody; (Obstetric Medicine), A. Blackstock; (Pathology), D. C. Clark, L. M. Moody; (Hygiene), L. M. Moody; (Psychological Medicine), A. N. M. Davidson.

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examinations indicated:

D.P.H.—F. J. Devlin, Captain R. A. Jones, Lieutenant N. Morris, Major R. S. Rodger.

UNIVERSITY OF GLASGOW.

THE following degrees were conferred on July 21st:

M.B., Ch.B.—J. S. Martin, J. Marshall, †R. Aitken, W. Adams, Janet M. Alexander, J. Ashforth, A. B. Austin, D. C. Buchanan, J. S. Craig, W. Dempster, M. Devers, K. H. Dyke, J. P. Fleming, T. Fleming, T. Forrest, W. W. Forsyth, R. J. L. Fraser, Jean M. Frew, G. K. Fulton, P. F. A. Grant, Grace L. Hunter, E. P. Irving, J. Joels, W. F. Kivlichan, Mary R. Knight, A. B. M'A. Lang, G. Lean, N. Mackillop, D. J. Mackinnon, Robina S. Mackinnon, Jessie B. MacLachlan, Lillias MacLay, W. M'William, D. S. Mitchell, J. Moffatt, G. Pearson, H. Robertson, J. J. Robertson, J. L. Rowlands, F. W. Sandeman, J. H. Shearer, D. Taylor.

* With honours.

† With commendation.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THE following gentlemen have been admitted Fellows: T. Ewing, W. L. Hodge, J. MacLean, W. W. Shorten, H. P. W. White, F. J. Woo.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates passed in the subjects indicated:

Surgery.—H. N. Dale-Richards, †L. E. A. B. Farr, †B. Ramirez *W. Stansfield.

Medicine.—C. W. Bower, †D. C. Clark, †H. N. Dale-Richards, †E. W. Diggett, †S. G. Mahomed, †E. J. G. Sargent, †G. R. Sharp, †F. V. Wynn-Wernick.

Forensic Medicine.—C. W. Bower, E. A. Leak, A. Magill, S. G. Mahomed, G. W. Pratt.

Midwifery.—A. E. Collie, G. W. Pratt.

* Section I.

† Section II.

The diploma of the society has been granted to Messrs. H. N. Dale-Richards, L. E. A. B. Farr, G. W. Pratt, B. Ramirez, and W. Stansfield.

Obituary.

DR. JOHN FRANCIS NEVILLE, of Newport, Mon., who died at Llandrindod Wells on July 14th in his 50th year, was born at Ahavine, near Youghal, co. Cork, was educated at Queen's College, Cork, and obtained the diplomas of L.R.C.P. and S. Edin. in 1895. He went to Newport, Mon., in 1896 as assistant, and afterwards started practice for himself. During the twenty years of his professional life in Newport he lectured to ambulance classes organized by the employees of the Great Western Railway Company, and as an acknowledgement for these gratuitous services was some years ago enrolled an Honorary Associate of the Order of St. John of Jerusalem. He was a member of the Monmouthshire Division of the British Medical Association, and was a frequent speaker at the discussions which took place at the inauguration of the Insurance Act. Though he laid no claim to oratory he had a humorous way of pointing his arguments which made him an acceptable debater. He practically died in harness, having worked until within a week of the end. He was a bachelor and is survived by two sisters. The writer enjoyed the privilege of a close friendship with the late Dr. Neville for twenty years, and for that reason can appraise his many good qualities. He was frank, generous, open-hearted, and relieved much suffering among the poor without fee or reward. Before his health began to fail he had a genial, sunny disposition, which attracted to him hosts of friends as well as patients. He was perhaps seen at his best when dispensing hospitality. As a colleague and friend he was loyal and devoted; his opinion on medical problems was always shrewd and sound. His busy practice made many demands on his leisure, but he was one who loved work and also enjoyed life to the full. He might have taken the lines from Horace's Ode (iii, 29) as his motto:

Ille potens sui
Laetusque deget, cui licet in diem
Dixisse vixi.

DR. AUGUSTUS W. THOMAS died at his residence at Swaffham on July 19th, aged 58. He received his medical education at University College, London, and the University of Edinburgh, and took the diplomas of L.R.C.P. and S. Edin. in 1882. He then assisted his father in practice and subsequently succeeded him. He was surgeon to the Swaffham Cottage Hospital, M.O.H. for the Urban District Council, and district and workhouse medical officer of the Swaffham Union. He took great interest in the volunteer movement, and had passed through all the grades of officership in the V.B.N.R., which subsequently became the 3rd Battalion of the Norfolk Regiment. After the outbreak of war he commanded his battalion for some time. He was the representative of the West Norfolk Division of the British Medical Association. He leaves a widow, two sons, and three daughters.

DR. JOHN DESCARRIERES BALLANCE, of Carbis Bay, Cornwall, died recently, at the age of 57, from heart failure. He studied at St. Thomas's Hospital, and took the diplomas of L.R.C.P. Lond. and M.R.C.S. Eng. in 1887, and held the post of resident accoucheur at his hospital. He subsequently held the offices of assistant surgeon to out-patients at the Evelina Hospital for Children, London, and resident medical and surgical officer at the Jaffray Suburban Hospital, Birmingham. Prior to retiring to Cornwall he was in practice at Edgbaston. He was a member of the West Cornwall Division of the British Medical Association.

DR. DAVID CARRUTHERS died at his residence at Muirkirk on June 8th. He was a native of Kirkpatrick-Fleming, received his medical education at the University of Glasgow and took the diplomas of L.R.C.P. and S. Edin. in 1881. He became assistant to the late Dr. Ritchie, and succeeded to the practice. He held the offices of medical officer to the parish council, the post office, and the Scottish Education Department, as well as certifying factory surgeon. He was a member of the Ayrshire Division of the British Medical Association, of which he was at one time chairman.

DEPUTY-INSPECTOR-GENERAL ALFRED WILLIAM WHITLEY, R.N. (retired), died of pneumonia at Ealing, on May 15th, aged 77. He was the youngest son of the late Rev. John Whitley, D.D., Rector of Ballymackey, and Chancellor of the Killaloe, and was educated in the medical school of the Royal College of Surgeons, Ireland, taking the L.R.C.S.I. in 1859, and the L.K.Q.C.P. in 1860. After serving as demonstrator of anatomy in Trinity College, Dublin, he entered the medical department of the Royal Navy, from which he retired thirty years later, on May 19th, 1894, with the rank of deputy-inspector-general. He was awarded a Greenwich hospital pension on December 5th, 1909.

COLONEL JESSE GRIGGS PILCHER, Bengal Medical Service (retired), died in London on July 3rd, aged 78. He was born on March 25th, 1839, educated at Dublin and at Edinburgh University; he took the diplomas of L.R.C.S. Ed. and L.A.H. Dub. in 1858, and M.R.C.S. in 1860, also the F.R.C.S. Eng. in 1869. He entered the I.M.S. on October 1st, 1860, one of the last batch gazetted before the service was closed for five years, became surgeon on October 1st, 1872, surgeon-major on July 1st, 1873, brigade-surgeon on May 14th, 1888, and deputy surgeon-general on March 29th, 1890, retiring on March 29th, 1895. Most of his service was passed in civil employ in Bengal, where he was for long civil surgeon of Howrah, and latterly for two years of Darjiling. After acting for a short period as Inspector-General of Civil Hospitals in Bengal, he filled that post in the North-West Provinces for his last five years' service.

LIEUTENANT-COLONEL ALBERT WILLIAM DENIS LEAHY, Bengal Medical Service (retired), died in London, after a long illness, on July 17th, aged 61. He was born on July 20th, 1855, and educated at Charing Cross Hospital; he studied also at Vienna, Strassburg, and Paris, and took the diplomas of L.S.A. in 1877, of M.R.C.S. in 1878, and of F.R.C.S. in 1881, and the degree of M.D. Durh. in 1893. After acting as house-surgeon at Charing Cross Hospital, he was appointed assistant surgeon to Westminster Ophthalmic Hospital and lecturer on anatomy to the School of Medicine for Women. He entered the I.M.S. as surgeon on September 30th, 1882, passing in first, became surgeon-major on September 30th, 1894, and lieutenant-colonel on September 30th, 1902; he retired on June 5th, 1903. During his service in India he held many important appointments. After two years' military duty and a short spell as surgeon to the Viceroy, Lord Dufferin, he entered the political department and served successively as residency surgeon at Kotah and at Baghdad and as civil surgeon of Quetta. About 1890 he was transferred to Bengal as civil surgeon of the 24 Parganas (Calcutta), and during the next ten years acted at different times in several of the professorships of the Calcutta Medical College—anatomy, surgery, ophthalmic surgery, and materia medica. He accompanied the Afghan Shahzada, son of the Amir Abdur Rahman, on his visit to Europe in 1894. During his last two years in India he was civil surgeon of Darjiling.

SURGEON-MAJOR GIRDHARLAL RATANLAL DAPHTARY, Bengal Medical Service (retired), died at Hammersmith on May 26th, aged 71, and was cremated at Golder's Green on May 31st. He was born on August 4th, 1845, and educated at the Grant Medical College, Bombay, and at Glasgow University, where he graduated M.D. in 1871, after taking the diplomas of M.R.C.S. and L.S.A. in 1870. He entered the I.M.S. as assistant surgeon on March 30th, 1872, became surgeon on July 1st, 1873, and surgeon-major on March 30th, 1884, and retired on February 17th, 1890. He served in the Afghan war of 1878-80, and received the medal.

HONORARY SURGEON WILLIAM KARNEY, Indian Subordinate Medical Department, Madras (retired), died at Madras in April, aged 83. He entered the I.S.M.D. over sixty years ago, was promoted to an honorary commission on February 12th, 1879, and retired on November 21st, 1889. He served in the Indian Mutiny, and in the second China war of 1859-60, and subsequently for many years held the post of assistant professor of materia medica in the Madras Medical

LIEUTENANT-COLONEL KARABA RAMCHODDAS KIRTIKAR, Bombay Medical Service (retired), died at Bombay on May 9th, aged 68. He was educated at the Grant Medical College, Bombay, and at University College, London, and took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1876. Entering the I.M.S. as surgeon on March 31st, 1877, he became surgeon-major on March 31st, 1889, surgeon-lieutenant-colonel on March 31st, 1897, and was placed on the selected list in 1902, retiring with an extra compensation pension on May 24th, 1904. The first five years of his service were spent on military duty, and during this time he served with the 19th Bombay Infantry in the second Afghan war in 1878-80, serving in the Girishik column, taking part in the battle of Maiwand and in the siege of Kandahar, and receiving the medal. In 1886 he was appointed to officiate as professor of anatomy in the Grant Medical College, Bombay, and as second surgeon to the Jamsetji Jijibhai Hospital. Subsequently he acted as professor of materia medica and of botany, successively, and as health officer of Bombay. In 1898 he became civil surgeon of Ratnagiri, where Thibaw, ex-king of Burma, and his family were in his medical charge. He was a botanist of repute, the author of works on *The Poisonous Plants of the Bombay Presidency*, and, with Major B. D. Basu, of *Indian Medicinal Plants*. A third work on *The Cryptogamia of India* was left unfinished.

DR. F. F. ULRICK, of Copenhagen, who took a leading part in the movement for the better housing of the working classes in Denmark, died recently at the age of 93.

Medical News.

MAJOR SIR EDWARD WORTHINGTON, C.M.G., M.V.O., has been appointed Physician to H.R.H. the Duke of Connaught.

ON the recommendation of the fifth Latin-American Congress of Medicine, the University of Lima, Peru, has established a chair of tropical pathology. Dr. Julian Arce has been appointed professor.

THE price of the *Queen* has been raised to 1s. The last issue contains a photograph of the presentation of French decorations to members of the Scottish Women's Hospital unit and the first instalment of Mrs. Humphry Ward's new novel.

THE house of the Royal Society of Medicine (1, Wimpole Street, W.) will be closed for cleaning and library stock-taking during the month of August, but officers of any British medical service and of the American medical service will be admitted to the library between 11 a.m. and 6.30 p.m. every day except Sunday.

THE following officers represent the medical department on the staff of General Pershing, commanding the U.S. forces on this side of the Atlantic: Colonel Alfred E. Bradley, chief surgeon; Colonel M. W. Ireland, senior assistant surgeon; Major George Peed, second assistant surgeon; and Captain Henry Beeuwkes, junior assistant surgeon.

DR. JOHN S. MUIR, J.P., of Selkirk, celebrated, on July 12th, the conclusion of fifty years' professional work in that district. In 1886 Dr. Muir was president of the Border Counties Branch of the British Medical Association. For many years he was medical officer in the Border Rifles, and retired in 1905 with the rank of Lieut.-Colonel, and honorary Colonel.

ON July 9th Dr. Henri Roger was elected Dean of the Paris Faculty of Medicine in succession to the late Professor Landouzy. Dr. Roger is professor of experimental pathology and is the author of a work on infectious diseases and of a treatise on general pathology now in course of publication. He has also won distinction in the field of literature, and a play of his entitled *L'Epreuve*, produced at the Théâtre Antoine, had a considerable success.

AT the annual general meeting of the Medico-Legal Society of London, when the President, Sir Samuel Evans, G.C.B., was in the chair, a recommendation of the council that aliens of enemy nationality should cease to be either honorary or ordinary members of the society, was unanimously approved. It was announced that the ordinary work of the society would be resumed in October, when, after the delivery of the President's address, Dr. F. J. Smith will open a discussion on medico-legal points involved in the Criminal Law Amendment Bill. The honorary secretary is Dr. Crookshank, 15, Harley Street, W. 1.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

THE telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are: (1) EDITOR of the *BRITISH MEDICAL JOURNAL*, *Aitology*, *Westrand* London; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate*, *Westrand* London; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisecra*, *Westrand* London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

QUERIES.

H. has a patient with right-sided hemiplegia following cerebral haemorrhage three years ago. The leg is sufficiently recovered to allow slow walking, but much sleep is lost through tonic contraction of the extensor longus hallucis, with "cocking" of the big toe. Our correspondent seeks advice for the relief of this condition.

D. F. T., who holds the D.P.H., asks for names of books for a course of further reading. The following may be suggested: *Newsholme's School Hygiene: The Laws of Health in Relation to School Life*, rewritten by J. Kerr, M.A., M.D. (London: G. Allen and Unwin, Limited. 4s. 6d.) *Crowley's Hygiene of School Life*, by C. W. Hutt, M.A., M.D. Cantab., D.P.H. Ox. Second edition. (London: Methuen and Co. 1916. 3s. 6d.) *Occupations from the Social, Hygienic, and Medical Points of View*, by Sir Thomas Oliver, M.A., M.D., D.Sc., F.R.C.P. (Cambridge: University Press. 1916. 6s.) *Milk and its Hygienic Relations*, by Janet E. Lane-Clayton, M.D., D.Sc. Lond. Medical Research Committee Series. (London: Longmans, Green and Co. 7s. 6d.) *Rivers as Sources of Water Supply*, by A. C. Houston, M.B., D.Sc., F.R.S. Edin. (London: John Bale, Sons, and Danielsson. 1917. 5s.)

ANSWERS.

EXILED.—Judicious remarks on the training of memory in children may be found in the chapter headed "Mental Reproduction: Memory" (chapter ix, pp. 159-210, 1886 edition), in Professor James Sully's *Teacher's Handbook of Psychology*.

LETTERS, NOTES, ETC.

QUO VADIS (VEL CUI BONO)?

DR. ALBERT TEBB (London) writes to point out a blunder which may occur in the translation of the heading to a recent correspondence in the *JOURNAL*. Although *cui bono* could, without actual grammatical offence, be rendered by "what is the good?" or "to what good end or purpose?" the true meaning of the phrase is different. It was, in fact, the *obiter dictum* of some Roman jurist, and as such passed into legal phraseology. It meant, and still means, "who got the plunder or the advantage?"—that is, "who benefited?" or "for whose benefit?" In obscure criminal cases, where there is difficulty in putting a finger upon one among several persons implicated, the line of search should be to find out who benefited by the crime. To use the phrase in any other sense is a mistake.

CLINICAL ORGANIZATION OF THE MEDICAL PROFESSION.

DR. JAMES HAMILTON (Chelsea) writes: As the years pass senior practitioners lose knowledge of hospital staffs, especially of the rising juniors, and consequently are frequently in a difficulty when asked to name a consultant. Some plan on the lines suggested by Dr. Hawthorne at the annual meeting of the Metropolitan Counties Branch would serve as an introduction and be mutually advantageous.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under
Each additional line
A whole column
A page

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

THE INVESTIGATION OF THE SIGNIFICANCE OF DISORDERS AND DISEASES OF THE HEART IN SOLDIERS.

SIR T. CLIFFORD ALLBUTT, K.C.B., M.D., F.R.S.,
REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF
CAMBRIDGE;
PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION.

DR. LEWIS'S Report on the work done at Mount Vernon on Disorders of the Heart¹ as seen in the soldier is so careful and complete that there is little, at present, to add to it, and the comments I am requested to make upon it can be but few.

One main result of the investigation is to strengthen the opinion which, before these researches were established, was gaining ground—namely, that "heart strain," a phrase a few years ago in common use and application, is a rare event. In the article on Stress on the Heart in Allbutt and Rolleston's *System of Medicine*, an article which expressed the opinions at that time of Roy, Michell, and myself, we likewise had affirmed that "for one case of disability due to strain, or even of sharp overstress, there are fifty of secondary and incidental derangement." And again: "As the animal mechanism attained many wider and more various powers of survival yet scarcely even a momentary independence of the heart, this organ must itself have attained to an enormous endurance, and resources almost illimitable." But in the same essay, under "Infections," I said that "stresses upon hearts under this detrimental result only too often in (heart) strain..." "experience inclines me more and more to refer cases of heart strain to this category"; and I quoted Dr. Arthur Lambert of Harrow who "regarded in (1904) the specific fevers as the determinant of heart strain in schoolboys; anaemia, general debility and lack of training being subordinate causes. Up to 1903," he added, "I was able to collect a number of cases of 'heart strain,' and during those years influenza was always with us. After 1904 we saw very little of heart strain." With acute cardiac dilatation after such obvious infections as of scarlet fever and diphtheria we are all familiar, and in the article from which I am now quoting I stated that even a "bad cold" might have some such consequence, if during the brunt of it excessive exercise were undertaken.

It was in 1903, when de la Camp's paper² came into our hands—a paper in which the author reported, rather to our surprise, that the heart, far from expanding during muscular effort, diminished in mean diameter—that, infection apart, we began to take a different view of cardiac conditions under effort; that, instead of working under dilating stresses, the heart under exertion is normally smaller. Yet had we considered cardiac physics more intimately, we need not have been surprised. It is true that in exercise beyond the capacity of the myocardium the blood is heaped up in and near the right heart at the gates of the lungs; and this the more when the individual is imperfectly trained, or is becoming stale. But as rate and velocity increase, and the periphery expands, the output per beat must be less; and therewith the cardiac diameter. Furthermore, as the heart has its own blood supply, blood runs round the heart many times for once round the systemic area.

The heaping up of the blood in the right heart and veins is heavier, and tarries longer, in the untrained. Training is something far more than dietetics and muscular exercise; in the circulatory concert it means a development of the thorax, an unfolding of the lungs, and a swifter interplay of vascular, nervous and chemical responses.

In former papers I have described how in the first few minutes of increased effort—for example on starting to climb a steep hill—the arterial tree, as represented by its radial branch, opens out, not gradually but suddenly; and the better the training the sooner this expansive readaptation takes place. Under this change—this great reduction of friction—it is intelligible that the diameter of the left ventricle should diminish, or the chamber empty itself more completely. But in a man growing stale under training the vasomotor mechanism loses its tone, and its responses are enfeebled. There is no better test of the "fitness" of an athlete than to draw the finger-tip sharply down his cheek, when, if he be "stale," the red line will be strong and persistent. In many cases of "D.A.H." at

Mount Vernon this loss of vasomotor tone is conspicuous. The hand when hung downward turns a dusky blue, and its vessels empty when it is held above the head. If the finger be pressed upon such a hand and removed the white patch is long in recovering its colour.

But the researches of Dr. Lewis and Mr. Barcroft at Mount Vernon raise quite a new and a very interesting problem: setting aside for the while poisoning of the myocardium, may incidental infections produce any other effects in which the heart is concerned? The answer appears to be in the affirmative. These researches (p. 19) seem to discover a new disease, or rather to discriminate more exactly the features and nature of a disease less clearly apprehended already, by Da Costa and others, as "soldier's heart"; or by those of us who have written upon "neurasthenia" as "cardiac neurasthenia." The disease is one which is not uncommon in the civil population; but under the stress of the soldier's training, and amongst the aggregations of men in modern armies, it is more conspicuous and inconvenient. It is of the kind of diseases known to our fathers as "*morbi sine materia*"—a disease without a lesion. "Disease" is a clinical not a pathological term, and consists in a series of symptoms recurring with a fair uniformity. At Mount Vernon I have been much impressed by the uniformity of the series now chiefly under consideration. It consists in the main of the following terms or symptoms:—submammary pain, palpitation and quickened pulse, shortness of breath on exertion, tremor, exhaustion, "dizziness," and certain vasomotor phenomena. This group of symptoms is too uniform to be fictitious or fantastic.

Now it will be seen from the Report that in these cases—in this disease—although not rarely an infection takes some place in the history, the heart is mechanically unaltered. I am glad to add my testimony to the great care and precision with which these mechanical appreciations were carried out; the orthodiagraphic observations of Major Meakins and his colleagues being especially diligent and valuable.

The outcome so far then is that the fretful heart, known as the "soldier's heart," is not cardiac strain; and, whatever the explanation may be, for this I refer to the Report, there is this gain to nosology—that although, in the past, heart strain and what for temporary convenience I may call still "soldier's heart" have been confused, and even classed together, this disorder and that are now made separate and distinct. For "soldier's heart" we need a better name, and, if it is to be Greek, I have suggested ponopalmosis, a compound word which means palpitation on effort. Therefore, with a few chance exceptions, from the Mount Vernon category "heart strain" is dismissed.

Now by this selection I do not mean that heart strain does not occur; but that it is generally a result of some infection, is relatively infrequent, and does not constitute the bulk of the cases invalided from the army as "D.A.H." (see Report, p. 54 f.). With the gradual and inevitable deterioration of the myocardium after maturity—say in man from the age of 35 to 40 onwards—I have not now to deal. I have discussed this grave question in my *Diseases of Arteries*.³ At Mount Vernon nearly all the patients are under this period of life. This is one, and the first in importance, of the principles obtained under Dr. Lewis's research and direction. In the article referred to in the *System on Overstress of the Heart* the two classes of cardiac disorder were more or less confused; the cases which Roy and I and Michell studied were, many of them, it is true, cases of actual heart strain; but effects for the most part, if not in all instances, brought about under the influence of some infection. Moreover, in them the heart, the right side of the heart usually, was definitely dilated and the valves for a while often incompetent. In "D.A.H." the form of the heart is unaltered and the dyspnoea seems not to depend directly upon the heart.

Here however I would venture on some demur to the disrespect with which certain cardiac murmurs have been treated by Sir James Mackenzie—to whose researches we are all so deeply indebted—and by his disciples. This is an extreme reaction against the obsequious regard for these signals which not unnaturally prevailed in the generations immediately after Laënnec. It is true that in concluding "that the presence or absence of murmurs (wherever they may be audible) is of no value in estimating the soldier's

capacity for work." Dr. Lewis premises that he concerns himself only with the capacity of a man for military service for a subsequent period of undefined duration. This I agree is true; under my care at this moment is a man, aged 32, suffering from mitral regurgitation, now to the degree of large dropsy and dyspnoea, and in a condition beyond substantial remedy. He had rheumatic fever at the age of 6, and was then told that his heart was affected. But thereafter nevertheless for some twenty years or more he had been at work as a labourer. Last year I had a similar case in a man who, after rheumatic fever, with damage to the mitral valve reported at that time, had notwithstanding been occupied since as a coal-heaver for sixteen years; and for the while with impunity. Of such cases I think we must admit that though for many years the mitral regurgitant murmur had not indicated immediate physical incapacity, yet it did indicate cardiac disease, and sooner or later cardiac failure. That out of such a man the State may nevertheless get a few years' work, is a decision which at Mount Vernon we may very properly make without cynicism; as Dr. Lewis says, at Mount Vernon our business is only with capacity for farther service; still, as he admits, the diagnosis, or prognosis, is "open to criticism on academic lines";—that is to say, from the patient's point of view? And not the diagnosis only but also the rule of life.

Here may I remark that the phrase "back pressure," in common use even by expert writers on affections of the heart, is to me unintelligible. Surely by an increase of resistance in front the blood pressures must be raised in the whole area concerned; and equal in all directions, fore and back and lateral. To students at any rate, not to mention some of their seniors, this fallacious phrase suggests that the blood stream is reversed! In the generation of many a loud murmur the regurgitant wave, in the strict sense of the word, may be very small; possibly none, as a fluid vein and turbulent collisions of the particles of the blood may be caused by changes in the relative diameters of the chambers only. Or again, like a stream from a tap which when turned slightly on may be noisy, but when "full on" almost inaudible, so the slenderest thread of regurgitation may make a loud murmur. Constancy in the degree and quality of a murmur, as it suggests stability of structure and compensation is therefore, on the face of it, a good sign. In all cases of definite systolic murmur at the apex I believe there is regurgitation, whether the condition be temporary or permanent. I see no other explanation of the change of linear into turbulent motion.

In the class of cases we are considering, functional "murmurs"—that is murmurs dependent upon transitory causes—are very common: and I think we are bound not to ignore them but to do our best to analyse them and discriminate between them. This I think is not so difficult a task as it is often said to be. On the one hand in the "soldier's heart," as Dr. Levy pointed out to me, a systolic murmur having its chief seat along the left costal arch is very frequent; one would guess it to be but a whiff of air expelled at each jerky heart stroke from the lappet of lung. So again in the healthiest young man we may hear a systolic murmur over the area of the pulmonary artery; by this idle noise, although usually due merely to a slight impingement of the vessel upon the wall of the chest, and of no importance, many a lad has been kept out of the football field. Let us first eliminate all these insignificant noises from the list, and then on the other hand concentrate our more serious attention upon murmurs dependent on altered mechanical states of the heart; though, as even these are often transitory, a farther subdivision is necessary.

And for the present let us leave out of reckoning murmurs about the base of the heart, and direct our attention to those referable to the mitral and tricuspid areas. Even when these are transitory, as for example during convalescence from an infection, it seems certain that when systolic they signify valvular disorder; the valve, or more probably, in transitory cases, its bed, is awry; and the patient, so long as the murmur remains, should be treated on this assumption. For a murmur signifies the existence of an abnormal fluid vein, and an abnormal fluid vein means abnormal friction, and friction is a waste of energy. A young, vigorous, and normal heart, with some readjustment, may afford to waste this energy—for a while; but a perpetual waste, in an organ whose reserve is so precious, cannot go on without ultimate harm. It is a

handicap, and the efforts cast upon such a heart should not be immoderate.

In looking back upon many years of practice I recall very vividly, in respect of the present subject, the subsequent lives of many a patient in whom a mitral regurgitant murmur was for years the precursor of subsequent cardiac incapacity and ultimate failure. For the change from linear to vortex motion meant a fall in velocity, save in so far as the muscular structure of the heart at the part was buttressed. For many a year perhaps a young or comparatively young heart, out of its abundant stores, can meet excessive demands, and build itself up at threatened points; but if the interval is often a long one the event is none the less manifest. The murmur in crucial cases has been discovered accidentally; as for example in an examination for some temporary disorder, or for life insurance; though cardiac incapacity may not have ensued for years afterwards. After an uncertain period however the heart begins to enlarge, and the patient to feel a little transient dyspnoea on unusual effort; this symptom increases, and the heart begins to make itself felt; yet even thus the patient may live still for a few more years, and under due precautions do not a little work of a sedentary kind. It is then that effort tests may betray myocardial default, but the patient has then entered not upon his disease but upon the last stage of it. Then nocturnal dyspnoea will appear, the ankles puff up, and other symptoms of the final phase of the malady accumulate. Perhaps after this lapse of time I may refer to the first case of this kind of which I had any knowledge—that of my old master and friend Bence Jones. He bought a flexible stethoscope, then a novelty, and tested it first upon himself; unhappily a mitral regurgitant murmur made itself heard, and although this distinguished man lived on without suffering for a while, and in his impulsive way would still forget himself so far as to fly up the staircase at St. George's two steps at a time, yet gradually the increasing friction in the blood, and the consequent fall of velocity, made themselves felt, and brought about his premature death. Scores of such cases arise in my mind as I turn my eyes to the past; some of mitral regurgitation consequent upon an infection, some upon slow athero-sclerosis of the valve, and so forth. For, I repeat, an endocardial murmur means a fluid vein, an eddy; and an eddy means friction and a disturbance of linear motion; these, unless in some indifferent area, mean sooner or later a breakdown of the machine.

On one other point I would spend a few words—namely, on *latent mitral stenosis*. In consultation the question often arises whether or no in a particular case there is a murmur at the apex. "Murmurish," says one; another that the first sound is prolonged; another that the first sound is reduplicated, but no murmur. No "murmur," it is true; the added sound may not be murmuring nor whispering, but an addition to, or a hitch on the ordinary first sound. The first sound may seem divided, with a notch as it were, in the middle of it. Now the addition may be before or after the true first sound; in the latter case, sooner or later it murmurs more definitely, and betrays a mitral regurgitation. With this I am not now concerned; in the former case it is a sign of a mitral stenosis, slight in degree and "compensated." Now in this case a thrill—short perhaps, and narrow in area, but unequivocal—may, if carefully sought for, be detected. But in the absence of cardiac deformation, of definite murmur, and of proper symptoms, this thrill may not be looked for. These latent cases turn up in practice, civil or military, and, if not readily picked out, may be reckoned among "our failures."

As an illustrative example of latent mitral stenosis I may take the case of Mr. B., a patient of Dr. Johnson of Cambridge whom I had seen some years before for neurasthenia with irritable heart, to which he was, and still is, liable. Dr. Johnson sent him to me, in respect of a call to military service, with a note of a faint and variable presystolic murmur. He had had rheumatic fever but with no record of cardiac affection. The first sound was short and snappy, but his heart had always been irritable, and on this visit I could not hear any murmur unless it were, for a beat or two after putting him through some exercises, a very fleeting presystolic sound—so fleeting as to be hard to define or record. The heart's dimensions were to percussion normal. While murmur hunting I forgot till the last moment to feel for a thrill; but then I found a short apex thrill clearly perceptible, and presystolic in time.

Some ten days later I examined him again, and on this occasion a presystolic murmur was audible, brief and soft but decisive. Oddly enough, now the thrill had vanished; again and again I tried to find it but in vain. So capricious is this disease in its physical signs, and so elusive are its signs, in respect of military service or of life insurance. I am not as yet ready to accept a definite distribution of stenosis murmurs into early, middle, and late. Again, a young friend of mine, very active both in mind and body, and anxious to serve in the army, has been rejected on two occasions for "soldier's heart." He has a slight addition to the short first sound and a short presystolic thrill. He has never had rheumatic fever nor other illness.

We have had a complicated illustration of this phase in the Mount Vernon Hospital. With Dr. Wilson and another colleague I examined a man with the obvious signs of aortic regurgitation. The question arose whether or no a divided first sound, audible at the apex only, signified a reduplication of the first sound. This it scarcely seemed to be; the taps were too close and the first one too light and brief; but I thought I recognized in it such a split in the first sound as I have described. The carotid beat being, as usual in such cases, only too definite, we were able to conclude that the first tap of the duplex sound was presystolic. Following this up we detected a presystolic thrill, short and light but quite distinct.

A thrill must be very carefully placed and timed, for in many of these irritable hearts a systolic thrill can be felt; perhaps in most of them if some effort be made just before examination. It is short but often very distinct to the touch. It is not felt about the base of the heart, and is therefore not due to a slack aorta. How the thrill is generated it is not easy to say. Very often in these cases a systolic murmur at the apex is recorded, an alteration of the first sound, more like a prolongation of it with some change of quality than like a definite murmur of mitral regurgitation. To suggest the cause of this thrill is but to guess; but, if I may guess, my suggestion would be that in these cases the papillary muscles and their chords may be a trifle slack, so that the mitral sheets shiver a little in the current, as a sail shivers when the boat gets near the wind. Such a quaver would be transmitted to the ventricular wall, and thence to the thoracic. In such a condition there might well be a minute, inconstant, and insignificant regurgitation also; though ordinarily in mitral regurgitation there is no thrill.

In conclusion, I hope it may not be unbecoming in me as a member of the staff, but rather an onlooker than of effectual service, to offer my tribute of praise to the author of this Report; a brief summary of infinite pains, of his own and of those of his colleagues who are and have been on resident duty at the hospital.

ON GUNSHOT INJURIES OF THE CHEST.

With Especial Reference to Haemothorax.

BY

SIR JOHN ROSE BRADFORD, K.C.M.G., C.B., F.R.S.,
TEMPORARY COLONEL A.M.S., CONSULTING PHYSICIAN,
BRITISH EXPEDITIONARY FORCE.

WOUNDS of the chest do not as a rule reach the bases in France until the fourth day after the infliction of the wound, except in periods of heavy fighting, then they may arrive much earlier, that is, on the second day. The observations recorded in this paper deal more especially with cases observed from the third or fourth day up to about three weeks after the occurrence of the injury, and thus they deal with only a portion of the subject. Gunshot wounds of the chest are usually divided into those penetrating and involving the lungs or other thoracic viscera, and the non-penetrating, although it is not always possible to be certain during life that an apparent non-penetrating wound is really such. Non-penetrating wounds may, however, give rise to pleural and pulmonary lesions, and in a certain proportion of cases of simple clean perforating

bullet wounds of the chest the positions of the entry and exit wounds suggest that the bullet does not only pass through the chest but also through the lung, nevertheless there are no signs or symptoms indicating the presence of either air or fluid in the pleura, and such cases may recover rapidly and apparently completely. Pleurisy and empyema are the most common pleural lesions produced by wounds of the chest wall not involving the lung. The pleurisy is often at first dry, but not uncommonly an effusion follows, and since such lesions are often due to streptococcal infections spreading from the wound track in the chest wall to the pleura, an empyema of the usual type develops and requires the usual treatment.

Haemoptysis, haemorrhagic infiltration of the lungs, and pneumonia of a septic bronchopneumonic type are the pulmonary lesions that may follow on a wound limited to the chest wall. In addition to these, collapse of the lung of a massive type may occur on the side opposite to the injury even when the latter causes no pleural or pulmonary lesion on the side injured. The haemoptysis and the septic pneumonia are both directly associated with the bruising and consequent bleeding into the lung produced by the impact of the missile on the chest wall and the resulting injury to the chest wall and lung. The haemoptysis may not only be severe, but may also run a long course, and some of the most severe cases of haemoptysis seen by the writer in a very large series of chest cases were those in which the missile only bruised the chest and had not only not produced any wound, but where there was no evidence of any fractured ribs.

The bruised and blood infiltrated lung is very prone to become infected either from the lung or by the spread of infection from the wound track in the chest wall, and hence pneumonia of septic or of a bronchopneumonic type develops. In some cases wounds of the chest wall lay open the pleural cavity but do not involve the lung, a portion of the chest wall, more especially in its lower parts or at the back, is carried away and a gaping hole, often of considerable size, is left. In such cases the lung does not as a rule undergo complete collapse, although the pleural cavity is in free communication with the air. In fact, the volume of the lung seems to approximate to that seen after death when the pleura is open, and therefore the pulmonary collapse is markedly less than that seen in ordinary pneumothorax where, as is well known, very complete collapse occurs, yet in the latter cases the intrapleural pressure may not be above that of the atmosphere.

Penetrating wounds of the chest usually produce one or more of the following conditions: subcutaneous emphysema, haemothorax, pneumothorax, laceration of the lung. These conditions may not only arise where the wound is one obviously involving the chest, or where the wound of entry is near the chest—for example, the neck or the abdomen especially in its upper part; but wounds in other regions—for example, the face or arm—may also give rise to haemothorax or pneumothorax from the course of the bullet being peculiar owing to the position of the soldier at the moment he is struck. In such cases there is often only a wound of entry, and this may be small and inconspicuous, but yet a large haemothorax or even a pneumothorax may be present.

Further, in wounds of the chest the haemothorax or pneumothorax may be on the side opposite to the wound of entry; the missile taking an oblique course may enter on one side, more especially in wounds of the back, and follow such a course that it does not open the pleural cavity on the side of entry, although opening that on the opposite side without or with a wound of exit. Again, in some instances a bullet may enter and leave the pleural cavity on one side without causing any appreciable lesion on that side, and yet so wound the pleura and lung on the opposite side as to cause marked lesions.

Bilateral haemothorax is sometimes seen as a result of a single wound the track of which is transverse or oblique, and haemopericardium may occur in association with either unilateral or bilateral haemothorax.

Unilateral wounds, however, may cause bilateral effects owing to the development of contralateral collapse or contralateral pneumonia.

The subcutaneous or so-called surgical emphysema so often present in chest wounds is usually limited to the vicinity of the wound or to an area of the chest wall adjacent of variable size. In exceptional instances its

distribution is more extensive, and it may sometimes involve not only the trunk but even the whole body, including the face and extremities.

HAEMOTHORAX.

Haemothorax is the most common result of a chest wound: both pneumo-haemothorax and pneumothorax are relatively rare, and in a series of 328 cases of gunshot wounds of the chest only 8 cases of the former and 4 cases of the latter were observed.¹

The haemothorax may be either sterile or infected, and if the latter the infection may be either early or late. If early, the infection occurs within the first few days after the infliction of the wound, and is doubtless dependent upon infective material being not only carried in with the missile, but directly infecting the effused blood generally and rapidly. In such cases exploration of the haemothorax reveals the presence of organisms in the fluid withdrawn. Infection, however, may occur later, that is, in the second or third week after the receipt of the wound. Such cases may at first run the course of a sterile haemothorax, with but few symptoms, and the fluid removed by paracentesis may fail to show the presence of any organisms. Suddenly urgent symptoms, such as increasing fever, dyspnoea, pain, rapid pulse and jaundice, arise, and paracentesis then reveals the presence of organisms in the fluid withdrawn. The infection may be more or less localized, and more especially so in the lower portions of the chest, and in such cases paracentesis may yield different results according to the site explored; at one spot a sterile fluid may be obtained and at another at no great distance from the first a fluid of a totally different character containing abundant organisms. This is especially the case with anaerobic bacillary infections. It is probable that in many cases the explanation of the rapid development of the clinical picture of infection, in the course of what seemed for some days to be a case of simple sterile haemothorax, is to be sought in the fact that the infecting agent, that is, fragment of clothing, etc., was shut off by blood clot from the general mass of haemothorax fluid in the chest. Later, owing to the spread of infection through the clot, the haemothorax becomes infected as a whole, and hence the rapid development of urgent and very dangerous symptoms. In a series of 450 cases of haemothorax observed by Bradford and Elliott infection was present in 117—that is to say, roughly, in 25 per cent.; and Captain H. Henry, who carried out the bacteriological investigation, found that lung organisms such as the pneumococcus, *B. influenzae* and *M. tetragenus*, were present in some 20 per cent. of the infected cases, and that in the remaining 80 per cent. streptococci, staphylococci, and anaerobic gas-forming bacilli were found.

In approximately 50 per cent. of the infected cases anaerobic bacilli, either alone or in association with cocci, were present; hence it would seem that infection of a haemothorax is much more frequently derived from the skin or clothing than directly from the lung. In some instances the pleural infection arises from direct extension from the infected wound track in the chest wall, and such a mode of spread may lead to the development of pleural and pulmonary complications in cases of wounds limited to the chest wall, and not directly involving either the pleura or the lung.

Henry and Elliott² have studied the morbid anatomy of wounds of the chest in a series of 100 cases observed in hospital at one of the bases in France. These observations deal only with cases that succumbed from the third day to the third week after the infliction of the wound, and one of the most striking facts ascertained was, that within these limits of time, death from haemorrhage as a result of a wound of the chest was very rare. Thus, in a series of 78 fatal cases of simple haemothorax there were 70 in which either infection or an additional visceral complication, or both, were present. In the remaining eight cases, where death might have been due to haemorrhage, purulent bronchitis was present in three, and in four cases no record existed as to whether sepsis was present or not, thus leaving only one case in which haemorrhage alone could be definitely asserted to be the sole cause of death.

Septic infection is by far the most frequent, and therefore the most important, cause of death in cases of haemothorax that survive the first few days immediately following the wound.

Secondary haemorrhage is also extremely rare, and in this series of 100 fatal cases only three instances were recorded; in two cases the haemorrhage took place into the pleural cavity, and in one a fatal haemoptysis occurred from a vessel in the vicinity of a small abscess in the lung round a fragment of shell. The writer has only seen one other instance of fatal haemoptysis due to secondary haemorrhage in the course of observations on many hundred cases of gunshot wound of the chest, and here also it was due to the lesions produced by a fragment of shell embedded in the lung.

The more important points in the morbid anatomy of haemothorax are the following: The degree of collapse of the lung, and especially of the lower lobe, is very marked, and would seem often to be greater in amount than that usually seen in pleural effusions. The over-distension and so-called emphysema of the upper portion of the lung above the fluid is certainly far greater than that seen in cases of pleural effusion. The anterior part of the upper lobe of the lung is frequently pressed up against the chest wall, and the anterior margin of the lung frequently extends beyond the middle line. There may be a line of loose fibrinous adhesions gluing the surface of the lung to the chest wall at the upper limit of the effused blood. The parietal pleura in the area corresponding to the effused blood is coated with a layer of fibrin one-eighth to one-quarter of an inch thick, and the surface of the collapsed lung is similarly covered to a greater or less extent with a layer of fibrin. The collapsed lung on the side of the haemothorax rarely, if ever, presents signs of inflammation except in the immediate vicinity of the wound track in the lung or round any retained foreign body. Pneumonic consolidation is not found in the lung beneath the haemothorax. Purulent bronchitis may be present not only in the contralateral lung but also in the emphysematous portion of the lung on the side of the haemothorax, but above the fluid. The great collapse of the lung would seem to be not only a safeguard against further haemorrhage in cases where the lung is wounded, but also a very efficient protection against the development of inflammatory complications. There is some evidence to suggest that wounds of the apices of the lungs—that is, the portion that would collapse last—are associated with large collections of bloody fluid in the pleural cavity.

The bloody fluid present in the chest in cases of haemothorax consists in the main of defibrinated blood—that is, a mixture of serum and blood corpuscles, often presenting to the eye a considerable resemblance to blood, but differing from it in that it does not usually undergo massive clotting after removal from the chest. The parietal and visceral pleurae are covered to a greater or less extent with a layer of fibrin, and it is probable that the defibrination of the blood occurs as a result of the movements imparted to it by the respiratory and cardiac movements, and that it usually takes place very soon after the blood is poured out into the chest. Direct experiment has shown that the bloody fluid in haemothorax contains no fibrinogen, and hence, that although it resembles blood to the eye, clotting has really taken place, and that it is in reality defibrinated blood (Elliott and Henry).

Even in cases of sterile haemothorax the whole of the fluid in the chest is not defibrinated blood. This is shown by two facts: first, the cell content of the fluid is different from that of defibrinated blood in that an increased number of lymphocytes may be present together with endothelial cells, eosinophile cells sometimes in considerable numbers, and marrow cells; secondly, the quantity of fluid is sometimes very large, that is, four to five pints, and even then the patient may not show any gross or obvious signs of anaemia. Hence it is evident that there is some pleural exudate as a sequel to, and result of, the presence of the blood in the pleural cavity. In some cases further evidence of the presence of pleural exudate is afforded by the occurrence of a slight and peculiar clotting in the fluid removed from the chest by paracentesis. This clotting resembles that seen in the fluid of ordinary pleural effusions, but differs from it in that the coagulum contains abundant red corpuscles. This clot, although containing red corpuscles, is often scanty and generally gelatinous in consistency, and hence quite different in appearance from the clot formed from normal entire blood. The superficial resemblance of

this "secondary clotting," as it is termed by Elliott and Henry, to true clotting is readily explained, inasmuch as the pleural exudate has added coagulable material to the defibrinated blood present in the pleural cavity and the abundant red corpuscles present have been entangled to a greater or less extent in the coagulation. In a small number of cases defibrination of the extravasated blood would seem not to occur, and paracentesis then reveals the presence of a mass of soft jelly-like clot that blocks the needle and prevents satisfactory aspiration; presumably in such cases more or less massive clotting has taken place.

In infected haemothorax the pleural exudate is much more abundant, and hence numerous polymorphonuclear leucocytes are found on microscopic examination, and the fluid removed by exploratory puncture may yield a deposit of pus visible to the naked eye. The fluid itself is often of a crimson colour from the haemolysis that has taken place. Massive clotting would also seem to be more common in infected cases, since, both at operations and in the *post-mortem* room, large clots may be found, especially in the lower part of the pleural cavity between the diaphragm and the chest wall, and also in the vertebral groove. In these infected cases the inflammatory exudate is apt to be poured out rapidly, and a sudden considerable increase in the amount of fluid in the chest is often strong clinical evidence of the presence of infection, since, as mentioned above, secondary haemorrhage into the pleural cavity in haemothorax is very rare, and then only occurs in infected cases. In sterile cases there is neither secondary haemorrhage nor a sudden copious effusion to cause any sudden great increase in the amount of fluid present in the pleural cavity. In a considerable proportion of these infected cases there is not only a rapid pouring out of inflammatory exudate, but, in addition, there is gas formation, owing to the infection being dependent upon the presence of anaërobic gas-producing organisms. The development of gas is often very rapid, and such cases may present very urgent signs and symptoms that increase rapidly in the course of a few hours. In others the clinical picture is much less urgent, and in a few only slight symptoms are present, and the condition is only appreciated after careful examination.

The gas may be free in the pleural cavity, associated with very considerable collapse of the lung, and a variable but usually large amount of haemothorax fluid. In other instances the conditions are more peculiar; the collection of gas is localized above the haemothorax fluid, and below the emphysematous over-distended upper lobe of the lung. The loose fibrinous adhesions at the upper level of the fluid in the thorax are probably sufficient to tether the upper lobe to the chest wall, but whether this be the correct explanation of the non-collapse of the entire lung or no, the fact remains that the gas forms a localized collection above the fluid of the haemothorax and below the non-collapsed portion of the lung. Such localized collections of gas are usually in the lateral or postero-lateral regions of the chest, and more especially in its lower portions. The gas is usually offensive, and has either a definite faecal smell or else that of rotten eggs. It is often present under considerable pressure, and in the *post-mortem* room, if a cannula is inserted, the gas issuing from it readily burns, when lighted, with a bluish flame. In cases of this type there is often considerable displacement of the heart, and this displacement may develop with great rapidity—that is, 2 in. in twenty-four hours. In cases where the gas is free in the pleural cavity, the clinical picture is that of pneumothorax or pyopneumothorax; and where the condition develops rapidly the symptoms are apt to be urgent and the error may be made of regarding the case as one of progressive pneumothorax, whereas in reality the phenomena are due to the rapid formation of gas under pressure as the result of infection of the haemothorax fluid.

In infected haemothorax the deposit on the surface of the collapsed lung is much more abundant and thicker than in sterile cases, as a thick layer of lymph more or less organized is often present. This is of considerable importance, inasmuch as this deposit hampers the subsequent re-expansion of the lung after the removal of the fluid by drainage of the pleura. The longer the delay in draining the pleura in such cases the greater is the organization of this deposit, and therefore there is much risk of permanent incomplete expansion of the lung. The deposit on the pleura not only causes the re-expansion of

the lung to take place more slowly but also less perfectly, hence it is most important that cases of infected haemothorax should be treated and thoroughly drained at the earliest possible moment. Bilateral haemothorax is not very uncommon, and such collections are usually of small or moderate size; they may be either sterile or infected, and cases have occurred of bilateral infected haemothorax that have recovered after drainage of both pleural cavities. In bilateral haemothorax one side may be sterile and the other infected, and recovery has here taken place after aspiration of the sterile and drainage of the infected haemothorax. Bilateral haemothorax may be associated with haemopericardium, or in infected cases pericarditis may occur as a complication. The pericarditis seen in cases of infected haemothorax is probably usually of streptococcal origin, but in some instances an anaërobic infection of the pericardium may occur and then very striking physical signs may be present owing to the presence of gas and fluid in the pericardial sac. Two such cases have fallen under the observation of the writer and both recovered after opening and draining the pericardium. In one the condition was recognized as the result of the percussion of the pericardial area yielding a tympanitic note when previously a dull note due to the presence of effusion in the pericardium had been present. Pericarditis probably only occurs in infected cases, although pericardial friction and the signs of fluid in the pericardium may be detected in cases of sterile haemothorax, where, in addition to the pleural lesion, there is also the probability of injury to the pericardium and where x-ray examination may reveal the presence of a bullet in close proximity to the heart. The accurate diagnosis of such cases is often difficult, but it is probable, inasmuch as they often have no symptoms indicative of pericarditis, and they recover, that the pericardial physical signs are due to the presence of a haemopericardium rather than to a pericarditis with effusion. In the infected cases the presence of pericarditis is a very serious complication; in some there is merely greasy lymph, in others a moderate effusion, or where an anaërobic infection is present the pericardium may contain gas as well as an effusion. If the effusion is at all large in amount it is usually situated in the posterior part of the pericardium, and is therefore liable to produce some degree of pressure on and collapse of the lower lobe of the left lung. In very large effusions the transverse diameter of the pericardium is greatly increased. When the effusion is posterior in position, the heart may still remain in partial contact with the chest wall anteriorly, and thus, owing to the persistence of friction the presence of even a large effusion may be overlooked.

COMPLICATIONS.

The complications directly associated with haemothorax are few and are most frequently seen in cases of infected haemothorax. Purulent bronchitis, pneumonia, pleurisy, massive collapse of the lung, and pericarditis are the most common complications. Abscess and gangrene of the lung may occur, but these are dependent not on the haemothorax but on pulmonary lesions produced by the missile. One case of meningitis due to streptococcal infection in association with an infected haemothorax has fallen under my observation, but no case of cerebral abscess.

The relation of purulent bronchitis to haemothorax is often very doubtful, as it occurs so frequently apart from wounds, but many patients give a history that is suggestive of the onset of the bronchitis after the wound, although even in these it may be dependent on exposure. One of the most striking features of its distribution is its absence in that portion of the lung that is collapsed beneath the haemothorax effusion. Pneumonia, in various forms, may be present, but is not common, and here again the collapsed lung on the side of the haemothorax is not involved. It may occur on the side opposite to the haemothorax, but care must be taken in the diagnosis, as the physical signs of massive collapse present great resemblance to those of pneumonia, and, as will be mentioned later, contralateral collapse in cases of unilateral chest wounds is of quite frequent occurrence. There is, however, clear evidence from autopsy that pneumonia on the side opposite to the wound may occur in haemothorax. Septic bronchopneumonia is common in wounds of the chest wall not accompanied by haemothorax, where, as a result of the impact of the missile, the lung is bruised and haemorrhage

into its substance has occurred. Pleurisy, often dry, is also not uncommon on the side opposite to the haemothorax; this occurs most often in infected haemothorax, but some instances have been seen where there was no bacteriological proof that the haemothorax was infected. Pleurisy of a serious type, and often progressing to empyema, occurs as a result of injuries to the chest wall of a tangential character and associated often with fracture of one or more ribs. Septic bronchopneumonia may coexist in such cases. The contralateral pleurisy is especially prevalent in cases of streptococcal infection of haemothorax, and may also progress to effusion and the formation of an empyema. Such cases are necessarily very serious, and if, as is not infrequent, pericarditis is also present they are of the utmost gravity.

SOURCE OF THE HAEMORRHAGE IN HAEMOTHORAX.

There is some difference of opinion as to whether the injury to the chest wall, or that of the lung, is the more common cause of the haemorrhage into the pleural cavity, and it is not possible to dogmatize on this subject. Morbid anatomy does not yield any direct evidence of the bleeding having arisen from the chest wall, but it is obvious that it would be very difficult to exclude the possibility of the wound of an intercostal vessel. On the other hand, it is not unusual to find direct evidence of blood coagulation in the track produced by the missile in its passage through the lung, and the wall of the track is also infiltrated, to a varying depth, by extravasated blood. Henry and Elliott record in their series four cases of perforating wounds of the lower chest wall involving the pleural cavity below the area occupied by the lung and not wounding the lung, and where no haemothorax existed. Many instances of extensive injury to the chest wall opening the pleura have been seen where the lung itself was not involved, and where no haemothorax was present. The great rarity of secondary haemorrhage in cases of haemothorax is also in favour of the pulmonary origin of the bleeding, since the collapse of the lung associated with the haemothorax tends not only to check haemorrhage directly but also to prevent secondary haemorrhage owing to the rarity of septic inflammations in collapsed lung. It is probable, therefore, that in the great majority of cases of haemothorax the source of the bleeding is the injury to the lung, although cases may be seen occasionally where the haemorrhage is derived from a vessel in the chest wall, such as an intercostal or the internal mammary artery, or one of the big vessels at the root of the neck. Injuries of the great vessels of the neck sometimes coexist with haemothorax; aneurysm of the innominate artery has been seen in association with pneumo-haemothorax, but in such cases it is probable that the haemothorax is really independent of the arterial lesion and due to other pulmonary lesions, and the haemothorax or pneumo-haemothorax may be on the opposite side to that of the arterial lesion.

In rare instances the haemothorax fluid contains, in addition to blood, bile. The bile is derived from the wound track involving the liver, and in such cases the bile may reaccumulate in the pleural cavity after paracentesis has been performed and the haemothorax fluid drawn off. Repeated paracentesis may be required to draw off the reaccumulations of bilious fluid, and it is remarkable that jaundice does not necessarily develop in such cases, although the amount of bile present in the pleural cavity may be very large. This is further evidence that the pleural cavity in cases of haemothorax does not readily absorb fluid, and the lack of absorptive power is probably in part dependent upon the fibrinous coating on its surface, and in part, perhaps, on the lack of efficient respiratory movement on the injured side. In one case there was evidence of the presence of stomach contents in the haemothorax fluid.

SIGNS AND SYMPTOMS OF HAEMOTHORAX.

Dyspnoea, although often at first urgent, diminishes rapidly, and even when the quantity of fluid in the chest is large—that is, over three pints—it is not usually a marked feature after the first three days. It is, however, greatly increased by exertion and movement, and hence many patients on arrival at a base hospital after a long journey often have considerable dyspnoea and distress for twenty-four hours. Moderate pyrexia is usually present, and it may rise to 103° F.; but the pulse is not much accelerated,

and is usually under 100, and the patient does not have much distress unless cough is severe, frequent, and painful. The continued presence of high fever, pain, distress, rapid pulse, and furred tongue should always suggest the possibility of the haemothorax being infected, and a sample of the fluid should be removed with an exploring syringe without delay in order to determine this point by bacteriological methods. Jaundice is an important sign, as, if marked, it is a characteristic sign of infection, and more especially infection with anaerobic bacilli. In simple sterile haemothorax only a slight icteric tinge is present in the conjunctiva, but in anaerobic infections a deep yellow jaundice involving the skin generally develops, often with great rapidity. Such a jaundice is often misinterpreted as indicating a wound of the liver, especially when the wound is in the lower chest, but jaundice is quite exceptional in liver wounds, whereas it is a very characteristic sign of infected wounds, and especially of anaerobic infections. It may also, of course, be seen in the course of streptococcal infections.

The physical signs produced by haemothorax present considerable variety and often are very difficult to interpret. They are much more complex than those usually regarded as characteristic of simple pleural effusion.

One outstanding sign, easily demonstrated by percussion and confirmed by x-ray examination, is that the diaphragm on the affected side is much higher than normal. The high level of the diaphragm is most easily demonstrated in left-sided haemothorax, since then the tympanitic percussion note due to the stomach resonance is readily obtained high up in the axilla, and also in the antero-lateral region of the chest. In some instances this tympanitic stomach resonance may reach so high a level as to merge into the area of skodaic resonance in the infraclavicular region above the level of the fluid, and unless care is taken a mistaken diagnosis of pneumothorax may readily be made. X-ray examination often reveals that the diaphragm is not only high but also immobile. The skodaic resonance obtained in the upper chest above the level of the fluid is usually much more marked and much more extensive in its distribution than that present in ordinary pleural effusion, and not infrequently extends beyond the middle line, and this fact again is liable to lead to confusion of the condition with pneumothorax. The distribution of the skodaic resonance is confirmed by the observations on the morbid anatomy, as these show that the upper portions of the lung, especially anteriorly, are greatly over-distended and emphysematous, and that quite frequently the upper lobe is so over-distended as to extend well beyond the mid-sternal line.

The high level of the diaphragm, notwithstanding the presence of a large amount of fluid in the chest, and the very extensive and marked skodaic phenomena are two striking features of haemothorax and are in contrast to what obtains in simple pleural effusion. Over the area occupied by the fluid, blowing tubular, or even cavernous, breath sounds are frequently heard on auscultation. They are not only more marked than those occasionally heard over pleural effusions, but they are also heard over a much larger area, instead of being limited, as in pleural effusion, to a small area in the vicinity of the angle of the scapula.

Bronchophony and oegophony are also well marked and very definite; pectoriloquy is by no means rare. The physical signs thus often present a more or less clear resemblance to those usually regarded as characteristic of pneumonic consolidation, and it is not surprising that in a considerable number of cases where haemothorax is present, the erroneous diagnosis of so-called traumatic pneumonia is made. The signs described above are not present in all cases; in some the signs are similar to those found in cases of pleural effusion—that is, dullness, weakness, or absence of vocal fremitus, and weak or absence of breath sounds. Further, a case may present at an early period of its course the first set of signs with well-marked tubular breathing, and later on, with an increase in the amount of fluid, the second set with weak or absent breath sounds. This is more especially observed in infected cases where a rapid and considerable increase of the effusion may occur. In others where, as a result of the presence of anaerobes, gas is formed, a cracked-pot percussion note may be elicited often over a localized area where previously the percussion note had been dull. In these cases a bell sound may or may not be obtained, but the percussion note is quite characteristic.

Collapse of the Lung.

In ordinary pleural effusion the chest on the affected side is usually obviously enlarged, and the respiratory movements are diminished in amplitude; this is also true of some cases of haemothorax, more especially when the amount of fluid present is very large—that is, four to five pints. In a considerable number of cases, however, a very different condition is present, inasmuch as the chest is flattened and retracted on the side of the effusion, and the movements are so much diminished that the affected side is practically immobile. This retraction and immobility of the side may be present not only when the amount of fluid is small, but also in many cases where there is a moderate collection of fluid, approximately two pints in amount, but it does not occur in association with the largest collections. It is remarkable that in cases where retraction and flattening are quite marked, the apex beat may be displaced, as in ordinary pleural effusion, towards the opposite and unaffected side. This retraction of the injured side is a remarkable and common phenomenon in cases of haemothorax, and it seems to be a fact of the same order as the high level of the diaphragm already noted. Sometimes it is only seen in the first few days after the wound, and then, with an increase in the amount of the effusion in infected cases, it is replaced by bulging of the usual type. Well marked tubular or even cavernous breathing is heard on auscultation in those cases where marked retraction is present, together with bronchophony and pectoriloquy. The retraction of the injured side, the immobility of the chest and the high level of the diaphragm, would all seem to be due to extensive collapse of the lung or of the lower lobe of the lung, a collapse that is out of proportion to the amount of fluid present in the pleura, and is really very probably a collapse that is more or less independent of the presence of the fluid, and has some other mode of origin. It may well be that this collapse is a constant phenomenon in cases of gunshot injury of the chest, but that when a large haemothorax coexists its presence is naturally attributed to the mere effusion and its real nature is only obvious where it is clearly out of proportion to the effusion. Thus cases of massive collapse of the lung on the side of the injury have been observed by Bradford and Elliott where the amount of the effusion was so small as not to need aspiration, and where the signs cleared up and the lung re-expanded after a short interval. There are, however, other facts that may be adduced in support of the view that the collapse is more or less independent of the effusion. Thus it may occur on the opposite side of the chest to that injured, and not only is this the case, but it is probably of quite frequent occurrence, only the physical signs produced are erroneously attributed to the presence of contralateral pneumonia when contralateral collapse is really the condition present. The main distinguishing feature between the physical signs of pneumonia and those of massive collapse is the position of the heart's apex beat; in pneumonia there is no appreciable displacement, whereas in massive collapse the apex beat is displaced towards the collapsed lung. In an ordinary haemothorax affecting one side it may be impossible to determine clinically whether physical signs on the opposite side are due to pneumonia or collapse, since if the apex beat is found displaced, the displacement will necessarily be attributed to the presence of the fluid on the injured side. In such cases the diagnosis of contralateral collapse is largely an inference based on the absence of the clinical picture of pneumonia and on the rapidity with which the signs clear up, but in any given case there may be much doubt unless the diagnosis is confirmed by autopsy.

Contralateral collapse, however, has been observed in cases of wounds implicating the chest wall only, where physical examinations confirmed by x-ray observations showed that there was no lesion of the pleural cavity on the wounded side, the injury being a contour wound. Nevertheless, in such cases very extensive massive collapse has been present on the side opposite to that wounded and where there has been no retained missile or other foreign body. In some instances the massive collapse has involved the whole of the left lung and the displacement of the apex beat into the left axilla has been very marked. Such patients do not present the clinical picture of pneumonia, although the physical signs in the affected lung are very similar, and the patients' general condition of comparative

well-being, together with the absence of high fever, rusty sputum, etc., shows at once that they are not suffering from pneumonia. Further, contralateral collapse has been observed both during operation on the chest and also on autopsy. In one instance an exploratory operation was performed on a case of contralateral collapse under the impression that the physical signs indicated the presence of an intrapulmonary abscess.

Although the mechanism producing collapse of the lung on the side of the injury and on the opposite side is obscure and cannot be discussed here fully, the presence of this collapse is probably the explanation of the curious and characteristic physical signs so often present in haemothorax, such as the high level of the diaphragm and the frequent presence of tubular breathing, bronchophony, and pectoriloquy over the area of the pleura where fluid is present. This collapse of the lung must be regarded, therefore, as one of the leading, if not the leading, phenomenon of gunshot injuries of the chest. There is some evidence to suggest that it occurs early, soon after the infliction of the wound, as when cases are seen within a few hours of being wounded few physical signs beyond immobility and deficient air entry on the side of the injury can be detected. Such cases seen again twenty-four hours later may then show the ordinary signs of a haemothorax, but in their earlier phase the signs are often quite insignificant in comparison with the urgency of symptoms, such as distress and dyspnoea.

Displacement of the heart's apex beat is a valuable sign in haemothorax; sometimes it is of a simple character and similar to that seen in pleural effusion—that is, displaced to a varying degree away from the side of the haemothorax. In others the displacement is mainly dependent upon the presence of contralateral collapse, and, as mentioned above, in some of these cases, there is no pleural lesion—that is, no fluid, air, or gas in the pleura on the side of the injury—such cases may be misinterpreted unless care be taken in the examination. The displacement present in any given case may undergo an increase or a diminution. An increase in displacement is usually due to the haemothorax being really infected, and an increase in the exudation or gas formation has taken place in the interval between the two clinical observations.

A decrease in the degree of cardiac displacement in recent cases of haemothorax and occurring during the first week after the date of wounding is also not infrequent, and is often more difficult of explanation. It is commonly attributed to absorption of some of the bloody exudate; this, however, is highly improbable, since absorption from the pleura in these cases is extraordinarily slow and certainly does not occur to any appreciable extent in the early days after the wound. The return of the heart may be due to an alteration in the distribution of the haemothorax fluid dependent on increasing collapse of the lung on the side of the lesion, or else it may be due to disappearance of contralateral collapse. The degree of displacement of the heart in any given case is therefore a very uncertain guide of the size of a haemothorax.

DIAGNOSIS.

The main problem in diagnosis is the determination whether a haemothorax is infected or not, and this often presents difficulties, since a haemothorax that at first runs an apparently sterile course may be infected later, owing to the spread of infection either from the wound track or from some localized infection round a retained foreign body. In some of these cases of delayed infection, and more especially in those with anaerobic infection, the symptoms may develop with much rapidity, and be of such a character as to suggest the occurrence of secondary haemorrhage, where no haemorrhage has taken place. Rapid pulse, pallor, sweating, and collapse are not uncommon symptoms of a rapidly spreading anaerobic infection. Microscopic and bacteriological examination of the fluid withdrawn from the chest will generally determine absolutely the presence or absence of infection, provided care be taken to repeat the exploration and too much stress is not laid on the negative result obtained at the first puncture. It is often necessary to explore the chest at different levels. Cases are seen occasionally where the symptoms, and especially the character and duration of the pyrexia, suggest that infection is present, yet no bacteriological confirmation is obtained even with

repeated paracentesis. Such cases may get well with no special treatment after running a prolonged course of several weeks' duration. Their explanation is difficult, but it may be that the pyrexia in such cases is dependent upon the inflammatory process in the wound track, and more especially in that in the lung, and that the layer of fibrin coating the pleural surfaces prevents the infection reaching the pleural fluid. Care must always be taken in considering the diagnostic significance of pyrexia that it is not due to some associated complication, such as purulent bronchitis, contralateral pleurisy, pneumonia, or pericarditis, although all such complications are much more liable to occur in infected than in sterile haemothorax. The rarity of pulmonary inflammation in the compressed lung on the side of the haemothorax should always suggest, if symptoms are urgent, that infection of the fluid is present rather than pneumonia, although the physical signs may be such as to render diagnosis difficult. In all such cases there should be no delay in making an exploratory puncture, as it is essential for the successful treatment of infected haemothorax that the cases should be recognized as early as possible.

TREATMENT.

In sterile haemothorax, if the amount of the bloody effusion is small, there is no need for any special active treatment; such cases do well, although their progress may sometimes be slow. If the effusion is at all large in amount—that is, the dullness reaching above the angle of the scapula—the fluid should be removed by aspiration about the end of the first week after the wound. In a few cases earlier aspiration may be required to relieve distress arising mechanically from the amount of fluid present. Aspiration with oxygen replacement is better than simple aspiration, since by this method, with suitable local anaesthetics, the operation can be carried out without discomfort to the patient and without any of the symptoms that so commonly occur in ordinary aspiration, and not infrequently prevent by their urgency the completion of the procedure. Further, with oxygen replacement practically all the fluid present in the chest can be removed at one sitting; this is rarely feasible with ordinary aspiration, where the development of such symptoms as a sense of constriction, distress, cough, etc., occurs before all the fluid has been removed. These unpleasant symptoms develop as a consequence of a too sudden change in the intrapleural pressure resulting from the rapid removal of fluid, together with incomplete adjustment owing to incomplete expansion of the lung. Different patients vary considerably in the degree of their tolerance of pleural pressure changes, and these are necessarily much influenced by the degree and rapidity with which the lung re-expands. With an oxygen replacement apparatus a measured quantity of oxygen at any desired pressure can be introduced, and thus violent and sudden changes in the intrapleural pressure are avoided.

For practical purposes it is not necessary to measure accurately the intrapleural pressure; it is sufficient to regulate the introduction of oxygen by the presence or absence of symptoms. The aspiration of the fluid should be temporarily stopped when distress or a sense of constriction is first noticed by the patient; if the symptoms do not subside at once, a small quantity of oxygen from the oxygen replacement apparatus (Parry Morgan or other) should be allowed to flow into the pleural cavity. Then with the relief of all distress, a further quantity of the fluid can be aspirated and the process continued until the operation is completed. The patient is left at the end of the aspiration with a small quantity of oxygen in the pleura—for example, 200 to 500 c.cm. at a pressure considerably less than the pressure of the haemothorax, but still appreciably above the normal pleural pressure. The oxygen is gradually absorbed in the course of the following week, but it is remarkable that many days are required for the pleura to absorb even small quantities of gas, and this slow absorption is probably due to the coating of the parietal and visceral pleura with fibrin, as it is in remarkable contrast to the rapid absorption of air that is known to occur after opening the normal pleura.

Free drainage is required in all cases of infected haemothorax, and it is of the utmost importance that this should be provided as early as possible, as the organization of the deposit of lymph on the visceral pleura produces a great impediment to the rapid expansion of the lung after the

removal of the fluid, and this organization proceeds rapidly in cases where delay in operating takes place. Removal of the infected fluid by free drainage is, however, not sufficient treatment in all cases; the inflammation in the pleural sac and the septic clots must be treated by the local application of some efficient antiseptic, applied either by periodical washing out of the cavity or else by the instillation method and the Carrel-Dakin technique that is now so much used. If the cavity is treated by washing out, care must be taken to avoid raising the intrapleural pressure. Septic clots, often of considerable size, can be removed with success by this method. Recently the Carrel-Dakin technique has been applied with success to cases of infected haemothorax, and a few cases have already been so successfully treated that the operation would be required for the excision of the rib has been closed by secondary suture before the evacuation of the patient to England.

Two difficulties are met with in practice in cases of haemothorax. In one group of cases, although the pyrexia and the patient's general condition suggests the presence of infection, bacteriological examination does not confirm this. In another series of cases organisms are detected in the fluid, but there is little or no pyrexia, and the patient does not seem to be very ill. It is probable that some of the cases falling into this second group recover after simple aspiration, but their convalescence is often very slow, and certainly in some instances such cases develop serious and even urgent symptoms. For these reasons it is advisable to excise a portion of rib and procure free drainage in all cases of haemothorax where the bacteriological examination reveals the presence of pathogenic organisms, even if the clinical condition of the patient is not such as to suggest infection. As regards the first group, the position is more difficult, but it is probably wiser to delay opening the pleura until proof of infection in the fluid is obtained, as the pyrexia and even the other symptoms may have some other origin; it is a serious matter to open a sterile haemothorax in view of the possibility of secondary infection.

Care must be taken in selecting the site for excision of a portion of rib to provide really efficient drainage, and the fact that the diaphragm is abnormally high in these cases must be borne in mind, as otherwise the opening will be made too low down.

In some instances the wound of entry or exit communicates more or less directly with the pleural cavity and fluid in variable quantity drains from it; this drainage is rarely satisfactory or sufficient, and such cases require a counter opening in a suitable situation to really drain the effusion.

FACTORS IN FIELD AMBULANCE WORK WHICH HELP THE WORK IN CASUALTY CLEARING STATIONS.*

BY CAPTAIN K. M. WALKER, R.A.M.C.

IN spite of its necessary limitations, the surgery of the field ambulance is of the greatest importance. The treatment that a shattered limb receives during the first four or five hours may alter the whole future history of the case.

The surgery of the aid post and the dressing station is necessarily a surgery of emergency. Collection of the wounded, and rapid evacuation, must always be recognized as the most important functions of the field ambulance units; and when it is possible to do so, anything in the way of operative treatment must be postponed until the arrival of the wounded man at the casualty clearing station.

Haemorrhage.

In this surgery of emergency the treatment of haemorrhage takes first place, and there is a certain type of case in this connexion to which I should like to call attention. I refer to those cases in which there is a slow, continuous oozing that is at no time sufficiently rapid to be regarded

* Paper read at a meeting of medical officers of an army in the field.

as severe haemorrhage, but which in the long run may cause more loss to the patient than a brisker haemorrhage that has received prompt treatment. The danger of these cases is, of course, that they may not be recognized. A wounded man passes through many hands before he reaches the casualty clearing station, and although his dressings may have been changed on several occasions because they have "come through," no one may have been in a position to realize how much blood he has lost and how urgent is the call for prompt treatment. Such a case may not, indeed, be in danger of death from haemorrhage, but he will start his fight against *sepsis* severely handicapped. Every ounce of blood is of value to a wounded man, and the more efficient the work of an ambulance the less will be this avoidable loss. The wounds which are most likely to result in loss of blood in the above manner are compound fractures of the tibia and fibula, and wounds around the ankle-joint. Therefore, before dispatching such injuries from the dressing station, great care should be exercised in making certain that no oozing is taking place. The application of large quantities of gauze and wool to such cases is an "ostrich" policy as well as a wasteful one.

I have purposely dwelt on the less profuse forms of bleeding, for true arterial haemorrhage is not only rarer, but is so dramatic that there is no chance of its being overlooked. It is scarcely necessary to add that the application of a tourniquet to any case of haemorrhage must always be regarded as a purely temporary expedient. No case ought ever to leave a field ambulance with a tourniquet.

Splinting of Compound Fractures.

Another branch of field ambulance surgery that exercises a great influence on the future history of a case is the splinting of compound fractures, and especially of compound fractures of the femur.

It is during the first five or six hours after wounding that the danger of moving an unsplinted femur is greatest. When men with compound fractures of the femur die before reaching a casualty clearing station they almost invariably die of shock; and if anything is likely to aggravate shock, it is a long journey with a fracture that is imperfectly immobilized. I am aware of the difficulties that attend the use of a "Thomas" splint so far forward as an aid post, but one is stimulated to continue urging that something more should be attempted for these cases.

As the result of discussing these difficulties with various regimental and ambulance officers, I submit the following suggestions:

1. That nothing further should be attempted at an aid post than the simplest possible adjustment of a Thomas splint—that is to say, that it should merely be placed in position, traction made by a clove hitch round the ankle, and a sling tied behind the thigh.
2. That time be saved and exposure avoided by applying the splint over the clothes and without even removing the boots. Thus used, a Thomas splint should take less time to adjust than a Liston, and the task can be undertaken by any orderly.
3. That the more elaborate technique for completing the adjustment of the splint should only be attempted when the patient reaches more convenient surroundings.
4. That the Thomas splints supplied to the more advanced stations be rendered more portable by making the ring detachable. A dozen rings and a dozen bars could then be packed into the space now occupied by two Thomas splints.
5. That some exchange system between the ambulance advanced or main dressing stations and the aid posts should be maintained in order to ensure the supply of "Trench Thomas," in the same way as rules with stretchers and blankets.

I do not flatter myself that these suggestions entirely eliminate the difficulties that attend, and must always attend, any attempt to deal more efficiently with compound fractures of the femur at an early stage. They are offered tentatively, and if they do nothing else than stimulate discussion, and thereby assist at arriving at some practical solution of a difficult problem, they will not have been made in vain. The difficulty may be great, but the

necessity for improvement in dealing with these injuries is even greater.

Emergency Amputations.

Hopelessly shattered limbs should be amputated on arrival at the dressing station, if for no other reason than to relieve the wounded man of needless pain on his journey down the line. The operation is not a formal amputation; it is merely the completion of the work that the explosive has all but effected.

Chest.

It is often wiser to allow a chest case to remain quiet in the field ambulance rather than to subject him too soon to the dangers of a journey. When, therefore, it is possible to do so, perforated wounds of the chest should be retained in the ambulance until the dangers of shock and of haemorrhage have been weathered. Beyond the usual treatment there are only two points to be borne in mind. The first is that the sudden appearance of alarming symptoms in a case of haemothorax may be due to an anaerobic infection, requiring the immediate adoption of drastic measures—that is, drainage by resection of a portion of a rib. The second is that in the event of any likelihood of a gas attack, all chest cases must immediately be evacuated. Chest injuries and box respirators do not harmonize.

Head and Abdomen.

The more quickly head and abdominal injuries are evacuated the better. Owing to the difficulties of accurate diagnosis in abdominal wounds, it is better to err on the side of excessive caution, and to regard all wounds of the abdomen, back, and buttocks as potentially penetrating, unless there is clear evidence to the contrary. There is only one type of penetrating abdominal wound whose retention in a field ambulance is justifiable—namely, perforating bullet wounds of solid organs like the liver or kidney, in which it is certain that no hollow viscera are implicated, and in which there are reasons for suspecting haemorrhage. Such cases may be retained until the danger of haemorrhage is past, but to do this the diagnosis must be absolutely certain.

Shock.

In addition to these injuries, severe cases of shock should be retained until some reaction has taken place. Superficial and extensive lacerations often produce a disproportionate amount of shock like superficial and extensive burns. Such wounds are in no urgent need of surgical treatment, but are immediately dangerous only on account of the shock produced. For this reason the evacuation of such cases may be delayed until reaction has begun.

The improvement of the ambulance dressing stations and the increased facilities for surgical work that now exist should result in an improvement of the work performed there, rather than in an enlargement of its range.

Discussions as to the best type of dressing to employ in field ambulances are not, to my mind, very profitable. When the interior of a wound is full of dirt, cloth, shell fragments, and destroyed tissues, it matters little whether eusol gauze or cyanide be employed to the mouth of the wound. An alcoholic solution of picric acid is, however, more satisfactory than tincture of iodine, in that it is less irritating to the skin and at the same time more lasting in its effect.

I have avoided launching out into new ideas on the subject of ambulance surgery, and have merely selected a few points that seemed worthy of consideration. The casualty clearing station and the field ambulance are so closely connected, that anything that assists in bringing the work of the two into line must contribute towards efficiency.

THE Caledonian Hospital was opened recently in Brooklyn, New York. It is the first Scottish hospital established in the United States. Dr. William J. Cruikshank is president of the medical and surgical staff, and is head of the department of medicine. There are also departments of surgery, obstetrics and gynaecology, genito-urinary surgery, neurology, paediatrics, ophthalmology, laryngology, otology, roentgenology, and anaesthesia.

DERMATITIS DUE TO EXPLOSIVES USED IN AIR RAIDS.

BY

J. H. SEQUEIRA, M.D.LOND., F.R.C.P.LOND.,
F.R.C.S.ENG.,PHYSICIAN TO SKIN DEPARTMENT AND LECTURER ON DERMATOLOGY AT
THE LONDON HOSPITAL; HONORARY CONSULTANT FOR DISEASES
OF THE SKIN TO THE MILITARY HOSPITALS IN LONDON, ETC.

IN the BRITISH MEDICAL JOURNAL of June 30th, p. 894, I called attention to a form of dermatitis caused by the handling of powder from high explosive bombs and aerial torpedoes used in the air raid on June 13th. Many bombs have been dropped in various parts on previous occasions, but there had been no dermatitis of this particular type. It is evident that some new substance is being used.

Since my note appeared in the JOURNAL cases have been reported by Dr. J. W. Tyson,¹ whose patients were soldiers engaged in digging out bombs; by Dr. H. G. Adamson,² who saw cases at St. Bartholomew's Hospital simultaneously with mine at the London Hospital; by Dr. J. M. H. MacLeod,³ and by Dr. G. W. Sequeira.⁴ I have also had private letters from practitioners who have met with instances.

I have now seen 59 cases of dermatitis, 35 males and 24 females, and they fall into two groups. The majority following the raid of June 13th first attended the London

FIG. 1.

Hospital during the week ending June 30th, with a few stragglers in the next week. The later group, due to the July 7th raid, began to attend for dermatitis on and after July 18th. Four of these patients, two of the first group and two of the second, were shown at the meeting of the Dermatological Section of the Royal Society of Medicine on July 18th.

The irritant comes into contact with the skin in several ways. The following are characteristic instances:

1. A large number of workpeople were in a cap factory when the place was wrecked by bomb. The interior of the building and the material and made-up articles were covered with a yellow powder. The employees began to clear up the place and to resume work on June 15th. Their hands, and particularly the palms, were stained an orange colour, and vesication began on the night of June 23rd.

2. A man and a boy were buried in debris from the wreck of an office. To extricate themselves they had to make their way through much rubbish mixed with the yellowish powder. Their hands were stained at once, and nine days later vesication was noticed.

3. A man who had seen an aerial torpedo fall in a street on June 13th went out into the thoroughfare to obtain a souvenir. He picked up some of the powder, put it in paper, and took it home. His hands were stained, and although he did not again touch the powder the dermatitis began on June 23rd, and he has suffered severely.

4. Two women who walked through streets where bombs had been dropped suffered from dermatitis of the feet from the irritation of powder which had invaded the shoes.

5. An official at the London Hospital who was assisting relatives to identify the dead in the mortuary, a process necessitating examination of papers and clothing, has suffered from dermatitis of the foot, some of the powder having entered his shoe.

6. A small house was wrecked, and a woman occupier suffered in the usual way. Her four children were at school, and as the house had been demolished they were sheltered by neighbours.

The mother went in to attend to them, and they have been affected.

7. A young girl was admitted to the ward with injuries of the foot caused by a bomb. As she fell her hands came in contact with the powder, and although admitted at once to hospital the dermatitis developed after the usual interval.

SYMPTOMS.

The clinical picture is distinct. The initial staining is nearly always of a distinct orange tint. It is especially well seen on the palms. After the lapse of nine days (as a rule) the patients complain of intense irritation and itching, which interferes with sleep. This is followed by the appearance of closely set discrete vesicles the size of hemp seeds (Fig. 1). These are on the palms and along the sides of the fingers and in the interdigital clefts. The backs of the hands are swollen, and there are occasionally small vesicles the size of millet seeds. There is not much redness of the parts. The eruption of vesicles increases, and in many cases huge confluent blebs form, some of these are as large as a hen's egg. From one bleb 20 c.cm. of clear serous fluid was obtained, and in another instance the fluid dripped copiously from a ruptured vesicle. On the feet the phenomena are similar (Fig. 2), but the vesicles are rarely larger than a pea. In a few instances the lesion rapidly became infected and pustules formed, and in another a widely spread erythema with purpura on the lower limbs. The eruption is at its height about the fourth or fifth day, and the epidermis gradually separates, leaving a raw rather dry red surface. In some cases seen early the vesicles dried up with desquamation. In a few instances the feet were affected after the hands, probably by contact. Occasionally the face has been involved, and in one instance a widely spread eczematous eruption formed. Most of the patients were in a nervous condition when first seen, and in others this developed later from loss of sleep. In a few instances relapses are continuing, but are

FIG. 2.

not so severe as the primary attack. Patients who wore gloves to clean up their houses suffered most severely.

Pyrexia.

Three patients were admitted to the ward on account of the severity of the symptoms. One case ran an apyretic course; in two others the temperature reached 100° F. on two evenings.

BACTERIOLOGICAL EXAMINATION.

Dr. Western examined fluid from three cases. In the early stage the serum in the bullae was sterile. In one *Staphylococcus epidermidis albus* was found, and in another, already suppurating, *Staphylococcus pyogenes aureus*.

BLOOD EXAMINATION.

Dr. Panton found eosinophilia in three cases examined. In one instance 11 per cent. of eosinophiles were found, and in another 6 per cent. This was to be expected, and compares with Dr. Panton's report on trinitrotoluene cases.⁵

TREATMENT.

Prophylactic Measures.

It is important to avoid touching the powder or materials impregnated with the powder. Its removal can be effected by moistening a surface with a weak alkaline solution (one teaspoonful of sodium bicarbonate to a quart of water). Brushes may be moistened with this solution. If the circumstances permit, a hose may be used to wash down an apartment or surface covered with the powder. It is better not to wear gloves, as they soon become impregnated with the powder, and moist perspiring surfaces appear to be more easily irritated. Rags wet with the alkaline solution may be used.

If the skin of the hands is stained, an endeavour may be made to remove as much of the stain as possible by pumice, and by washing with the alkaline solution.

Treatment of the Dermatitis.

When the eruption has developed, the parts should be washed as little as possible, but the alkaline solution may be used without risk. I have found that the best local application is a liniment of calamine (calamine 70 grains, lime water 1 oz., olive oil 1 oz.). This rarely fails to allay irritation and to promote healing. If the parts become septic, the usual remedies are of service, and in a very bad case I found that spraying the parts daily with a malachite-green sublimate solution was of great value. The solution, which we owe to McIntosh and Fildes, is made as follows: Malachite green 1 part, hydrarg. perchlor. 0.5 part, spirit. vin. rect. 100 parts.

CAUSATION.

The substance which is the cause of the dermatitis appears to be hexa-nitro-diphenyl-amine. The phenomena are identical with those caused by aurantia, an orange dye (ammonium hexanitrophenylamine) which has been used for the dyeing of cheap brown shoes and other leather articles. In Prosser White's *Occupational Diseases of the Skin*, p. 99, "aurantia, emperor's yellow," is described as "a basic aniline azo dye," which causes an abundant uniform-sized crop of vesicles, thickly crowded together all over the palm. Cases were recorded by Radcliffe Crocker,⁶ whose description of the phenomena of aurantia dermatitis on p. 417 of his textbook on *Diseases of the Skin* (third edition) tallies exactly with the appearance and symptoms which have been observed in the cases now described.

The use of the substance was prohibited in Germany, and it is not used on either silk or wool in this country. In Thorpe's *Dictionary of Applied Chemistry*, vol. i, p. 340, it is stated that, according to Gnehm (*Ber.*, pp. 1246, 1557) and Bayer and Co. (*W. J.*, 1877, 879), aurantia produces skin eruptions. Martius contends that this effect is due to idiosyncrasy, and quotes the opinion of Salkowski and Ziureck in support of his statement. The ministerial order of November 8th, 1877, prohibiting its manufacture was cancelled in June, 1880.

I understand that hexa-nitro-diphenyl-amine is recognized as an explosive substance, and that it is combined with trinitrotoluene in the bombs which have been used in the recent air raids in this country.

I hope to be able to report later on some experiments which are being made with the substances in question, and would gratefully acknowledge the assistance afforded me by the officials of the Ministry of Munitions and the Medical Research Committee.

STATISTICS OF DEFECTIVE VISION OBTAINED AT A RECRUITING MEDICAL BOARD.

BY

CHARLES F. HARFORD, M.A., M.D., M.R.C.S.,
L.R.C.P.,

TEMPORARY CAPTAIN R.A.M.C.

The medical examination of the adult males of the country who are of military age affords an opportunity for inquiring into the incidence of disease which has never previously been obtained. In particular the ophthalmic centres attached to the recruiting medical boards have given facilities for estimating the relative frequency of ophthalmic disabilities in the different areas, which may be of some general interest and which should be of value in determining the suitability of different candidates for military service.

The accompanying table, prepared from the statistics of one ophthalmic centre for a period of six months, from June to November, 1916, may now be considered. At the outset it may be stated that the region from which the men were drawn included thickly populated suburban districts, country towns, and extensive agricultural areas, together with a few of the smaller manufacturing centres.

Table showing 2,640 Cases of Defective Vision seen at an Ophthalmic Centre between June and November, 1916.

1. Myopia :			
(a) In categories B 1 and C 1	951
(b) In categories B 2, B 3, C 2, C 3	523
(c) Classed as unfit	73
2. Hypermetropia :			
(a) In categories B 1, C 1	123
(b) In categories B 2, B 3, C 2, C 3	153
(c) Classed as unfit	2
3. Amblyopia	354
4. Corneal opacities	141
5. Traumatic cataract	119
6. Congenital cataract	44
7. Enucleation of eyeball	76
8. Fundus defects :			
(a) Choroido-retinitis	20
(b) Detachment of retina	9
(c) Retinitis pigmentosa	6
(d) Progressive optic atrophy	11
9. Night blindness, without special fundus changes			
...	3
10. Iritis	6
11. Nyctagmus	21
12. Miscellaneous :

(b) Chronic glaucoma	1
(c) Ocular paralysis with diplopia, etc.	2

2,640

The period is one of six months, and includes the time during which the men were called up who had been previously rejected for military service as being below the standard adopted in the British army for general military service. All the cases examined were those who were below this standard or who had been referred for ophthalmic examination on account of certain obvious defects. From this it will be seen that many cases of minor errors of refraction, or even some of graver eye troubles, may have been passed for general service if they possessed the visual acuity of R. $\frac{6}{24}$ L. $\frac{6}{60}$, which satisfied the military requirements for general service during the greater part of the period dealt with.

No attempt has been made to estimate the proportion of defective eye cases to the adult male population in general, for by far the larger part of healthy adult males had already been passed into the army, so that in these later months there has been a far larger proportion of defective cases, from whatever cause, many of these having been rejected in the earlier months of the war and being brought up again for examination and possible classification in some of the categories below that for general service. I will now discuss in detail some of the causes of disability which seem to be of greatest importance.

1. Myopia.—It will be seen that by far the most important question is that of myopia. Those who are affected by this refractive error are divided for convenience into three classes :

- Those whose defect can be corrected by glasses so as to fit them to shoot.
- Those who are below the standard for shooting but who might be fit for labour or sedentary work.
- Those who are unfit for any military service.

(a) The large number who are included under this head, nearly one-third of the total of cases of defective vision, indicates the importance of securing these men for service in the army. A considerable proportion of these could read $\frac{5}{6}$ with glasses, and the general standard adopted for this class was a visual acuity of not less than $\frac{5}{6}$ in the right eye after correction with less than -6 D. In the chief armies of the Continent these men would be accepted for the regular army.

(b) The next class includes those who could be corrected sufficiently with - glasses, such as were supplied during the period under review at Government expense (namely, a maximum of 6 D. spherical with + 4 D. cylindrical), if these would enable them to do labour or sedentary work. Some latitude has been granted recently to officers in charge of ophthalmic centres to order stronger glasses. No hard-and-fast standard was adopted in these cases, a decision being based largely upon the previous experience of the individual recruit. This class formed more than a fifth of the total, and if these are added to the total of the previous class the number of myopic cases

who could be selected as fit for some form of military service after correction amounted to more than one-half of the total of cases of defective sight.

(c) Only sixty-five cases were classed as unfit for any form of military service as a result of myopia.

2. *Hypermetropia*.—Cases included under this heading were again divided into classes (a), (b), and (c), as in the case of myopia. Before, however, commenting on these figures certain explanations should be made. It is obvious that a large number of men having slight degrees of hypermetropia would pass the War Office standard for general service, and therefore were not referred for special ophthalmic examination. On the other hand, a considerable proportion of cases included under the head of amblyopia were those in which one eye was amblyopic as a result of hypermetropia, and in many cases associated with strabismus. It will be seen, therefore, that the figures given do not afford an exact statement as to the incidence of hypermetropia among adult males in the same way as myopia. We may now deal with the subdivisions mentioned above:

(a) Only 123 cases were placed in the higher categories (B1 or C1) after the correction with convex glasses, and when this is compared with the similar figures under the heading of myopia, it appears comparatively insignificant. The fact is, as already explained, that most of the lower forms of hypermetropia are not likely to be a hindrance to general service even without the use of glasses. This no doubt accounts for the fact that the Continental armies seem to pay little attention to hypermetropia. If it is small it is of little significance; if it is high, the use of glasses is not likely in many cases to render the individual fit, at least for shooting units.

(b) A rather higher proportion of cases, 153 in all, were placed in the lower categories (B2, B3, C2, C3), in which great accuracy of vision may not be required, or in which clerical work could be performed with suitable correction.

(c) Only two cases were definitely classified as unfit on account of high hypermetropia. This is explained partly by the fact that even in the higher forms of hypermetropia examined the men were in most cases fit for some sort of military service with correction. It must also be remembered that some of these were included under the head amblyopia.

3. *Amblyopia*.—This heading is of no scientific importance, though it cannot be omitted from notice, as it helps to explain the inadequacy of the figures included under hypermetropia. By far the larger proportion of these were cases in which one eye was amblyopic as a result of hypermetropia, a few being due to myopia, and in many cases the amblyopia was associated with strabismus. No case of toxic amblyopia was noted.

4. *Corneal Opacities*.—One hundred and forty-one cases were recorded of opacity of the cornea in which this condition produced serious defect of vision in at least one eye, and it was only in a small number that both eyes were affected. Cases of obvious total blindness from corneal or other defects did not appear before the Board. Some cases of interstitial keratitis and of corneal ulcers still in an active stage were included in this series.

5. *Traumatic Cataract*.—This accounted for 119 cases, most of which had undergone some operative procedure. In nearly all cases there was no useful vision in the damaged eye, but the eye was quiet, and if the other eye had good visual acuity they were accepted for modified service.

6. *Congenital Cataract*.—This condition accounted for 44 cases.

7. *Enucleation of Eyeball*.—There were 76 cases in which one eye had been removed, usually, if not in all cases, as the result of injury.

8. *Fundus Defects*.—There were 20 cases of choroido-retinitis, 9 of detachment of retina, 6 of retinitis pigmentosa, and 11 of progressive optic atrophy. Defects due to myopia are not included under this heading. Probably there were numerous minor defects not seriously affecting vision, or at least in which the minimum requirements of the army were satisfied, so that there was no call for detailed examination.

9. *Night Blindness*.—In addition to the cases of retinitis pigmentosa there were three cases of night blindness in whom no fundus disease could be detected. These were cousins belonging to a family in which the condition only affected males and had been transmitted through females

from grandparents, the intermediate generation having been omitted. There were also three brothers with high myopia, one of whom had also some lens opacity, who had to be led from their work after dusk.

10. *Iritis*.—Iritis, whether recent or of old standing, was only recorded in six cases.

11. *Nystagmus*.—So-called "congenital nystagmus" was responsible for most if not all of the twenty-one cases included under this heading. There was associated defect of vision, and, owing to the exceedingly unsatisfactory results of the enlistment of men suffering from this condition, they were classed as unfit. No instance of "miner's nystagmus" was seen, there being no mining districts in the area.

12. *Miscellaneous*.—Among other defects there were two cases of vitreous opacity, one case of chronic glaucoma, and two cases of ocular paralysis associated with diplopia and other symptoms which rendered them unfit for any military service.

A METHOD OF SUPINATION BY PLASTER.

BY

P. J. VERRALL, F.R.C.S.,

TEMPORARY LIEUTENANT R.A.M.C.; CHIEF ASSISTANT, ORTHOPAEDIC DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL.

At the Military Orthopaedic Hospital, Shepherd's Bush, we see numbers of cases of gunshot wound of the upper limb in which the forearm is held more or less in a position midway between pronation and supination, and passive supination is impossible. This condition is due to the habit of putting up such cases originally either on an internal angular splint or even on a Thomas extension splint without due regard to the preservation of supination, which is notoriously the most difficult movement to restore. I have recently devised a simple and effective means of treating these cases by means of plaster. The plaster is

FIG. 1.

applied over felt (previously stitched together round the limb) and consists of two parts. A few temporary stitches hold the two portions of felt together while the plaster is applied, and are then cut. The upper reaches from the middle of the arm to the middle of the forearm; the lower from the middle of the forearm to just above the heads of the metacarpal bones, a hole being left for the thumb to protrude. On either side of the interval between the two portions pieces of metal (Fig. 2) are incorporated in the plaster. These consist of metal strips $\frac{3}{4}$ in. wide and 3 in. long, one inch of which is turned up at a right angle and the other

FIG. 2.

two inches notched to ensure firmer incorporation in the plaster, the notched corners being turned up to form spikes. One of these is fixed into the radial and another into the ulnar side of the lower part, and two other pieces are similarly inserted into the inner and outer aspects respectively of the upper part. When the plaster is firmly set (next day), pieces of rubber tubing are stretched round

these two pairs of metal pieces and gradually tightened from day to day, supination being complete when the two pairs are opposite one another. If desired, pronation can be obtained by reversing the process. It will be found necessary to put extra felt padding over the head of the second metacarpal, over the lower end of the radius, and over the ulnar border of the hand. When supination is complete the arm should be kept in this position for at least three weeks to prevent relapse before massage is begun.

This method is suited to cases of adhesions in the upper and lower radio-ulnar joints, fractures of the forearm where there is danger of cross union, and disability due to contracture of soft parts.

I am indebted to Colonel Sir Robert Jones, C.B., for permission to publish this article. The photograph was kindly taken for me by Mr. F. H. Lewis.

A SIMPLE MEANS OF ASCERTAINING IF A STERILIZING HUT IS HOT ENOUGH TO DESTROY LICE AND NITS IN CLOTHING OR BLANKETS.

By A. BACOT,

ENTOMOLOGIST TO THE LISTER INSTITUTE OF
PREVENTIVE MEDICINE.

The following method was planned in the first instance with a view to its possible service to sanitary officers who had to use extemporized sterilizing chambers, but a subsequent knowledge of the working of permanent hot-air sterilizing huts in home camps suggests that it might be of assistance to officers in charge of these also. Unless an electric ventilating fan, or other efficient means of circulating the air and so causing a uniform temperature throughout the chamber, exists, a stratified condition obtains, in which the heat is too low to kill at the lower levels and needlessly high at the top. For instance, door thermometers (that is, thermometers visible through a glass panel let into the door) record only the temperature in the vicinity at the level at which they are placed, and Captain J. T. Grant's trials with maximum thermometers have shown that, while the door thermometer records 60° C., the temperature just over the floor may be only 37° C., while at 7 ft. it is 103° C. The use of maximum thermometers placed at different situations within the chamber affords a useful check upon the record of the door thermometer, but may be deceptive, as only the extreme temperature is registered, there being no indication of the length of the period to which the clothes have been exposed to it.

By the use of porcelain pots or dishes of a definite surface area, containing a given quantity of stearin or paraffin wax of a suitable melting point, a sufficiently stable relationship between the heat and period required to kill both the insects and their nits can be established. In arriving at this relation a number of experimental trials must be made, but once the quantity and surface area required for a stearin or wax of a known melting point is settled only the simplest precautions are required to ensure efficiency. It is necessary that the wax or stearin should be replaced when it gets dirty, as otherwise its melting point may be reduced, and that the pots, which may either stand or hang, are not tilted at such an angle that the surface area is altered. Even if this last condition should occur, however, it will lead to an increased temperature or period of exposure being needed to melt the stearin, so that the error would be on the safe side.

I have worked out the following quantities in relation to the temperature and period needed for the destruction of the nits of *Pediculus humanus* when enclosed in a pocket made of khaki cloth as used for army breeches in France and the home service. The samples of stearin used were supplied by Messrs. Price, Ltd., and melted at 60° C., according to the trade tests. Nits, when protected by a single thickness of khaki cloth as above described, are killed by a fifteen minutes' exposure to a temperature of 52° C. As the method pursued in practice is to place clothing or blankets in a cool, or with the second and later batches in a warm, chamber, and count the exposure period from the moment when the door thermometer reaches the stated temperature, the same procedure was followed in the trial tests. The periods quoted, therefore,

always presuppose a gradual rise up to the temperature, except in the case of the precautionary tests dealing with a quick rise to a high temperature mentioned below. In order to allow an adequate margin for contingencies, the temperature and period required for the destruction of nits is assumed to be 60° C. for thirty minutes, thus allowing as a margin at least fifteen minutes in time and 8° C. The porcelain pots used were supplied by Messrs. Price, Ltd.; they are those commonly used in the trade for samples of tallow, stearin, etc., and should therefore be easily obtainable. They are 2½ in. deep by 2½ in. in diameter; if only smaller or larger ones are obtainable the quantities of stearin used must be reduced or increased accordingly. The stearin must, of course, be melted in the pot and allowed to cool before use; 7 grams of stearin (trade melting point 60° C.) require thirty minutes at 60° C. under the conditions named, a small portion being still unmelted after twenty-five minutes; 10 grams require between forty and fifty minutes to completely melt it, only a narrow ring being melted within thirty minutes.

If two pots, one containing 7 grams and the other containing 10 grams, are placed or hung slightly below the level of the lowest garments in the sterilizing room, one can be sure, if all the stearin in the 7-gram pot is melted before the removal of the garments, that the exposure has been sufficient, both as regards period and heat; while, if all the stearin is melted in the pot containing 10 grams, it will show that greater heat or a longer exposure than was necessary has been used.

The question of the possibilities of an altered relation between the melting of the stearin and the killing of the nits with a short-period exposure to a higher temperature was tried. Nits and stearin were exposed together, and it was found that the stearin was more resistant to these conditions than the nits. For instance, when the temperature was rapidly raised from 21° C. to 80° C. within twenty minutes, the nits were killed while the 7 grams of stearin was not quite all melted. A rise to the same temperature in eighteen minutes showed the same result. A rise to 82° C. in fifteen minutes was just sufficient to melt all the stearin, the nits being killed. Again, a rise in twelve minutes to 81° C. killed the nits, but left a central disc of stearin unmelted.

MEDICAL, SURGICAL, OBSTETRICAL.

MECHANICAL AIDS IN A FIELD OPERATING THEATRE.

This short description might have been headed "The Mechanical Orderly," as most of the devices are made with a view to releasing the services of a trained man.

Fig. 1 represents a webbing loop and a length of tent rope with runner and button. The rope is looped round bars (½ in. water pipe is useful) placed some 7 ft. 6 in. high

FIG. 1.

and parallel to, but away from, the foot and sides of the table. By placing the loop round ankle or wrist the elevation and the degree and direction of traction on the limb can be instantly adjusted. A stretcher sling unpicked to its full length makes

four loops. It is specially useful in fractured thigh cases.

Fig. 2 shows a very simple arm rest made from two pieces of wood and two wide strip-iron hooks. The table portion should be 19 in. by 9 in., and the thinner piece, half of which is screwed to the under surface of the former, is 40 in. by 4 in. The thin portion goes under the top of the operating table, and the hooks then engage with

FIG. 2.

the bar side of the same. It is very useful for forearm cases and intravenous saline infusions.

Fig. 3 is a "chest rest," and replaces the unsatisfactory sandbag for keeping chest, back, buttock, and lumbar cases in the required posture. The trunk rests on the flat portion, which lies on the table, and the chest, shoulders, buttock, or abdomen, rest against the inclined plane according to the position desired. The base and inclined plane are padded and covered with jaconet.

FIG. 3.

Measurements: Base 22 in. by 6 in., upright 9 in. by 6 in.

Fig. 4 is a useful little box for the anaesthetist, made of a piece of wood 24 in. by 4½ in. and two of the larger shaped blocks out of 18-pounder shell boxes, forming two round wells 2½ in. deep and 3½ in. across. One of these holds comfortably an ordinary 8 oz. bottle for ether and a flat 4 oz. (or Mills's drop) bottle for chloroform. The thin end slips under the pillow, or the end of the waterproof palliasse of the table, and the whole takes up very little space in cramped quarters.

FIG. 4.

Fig. 5 is a webbing strap about 45 in. long, with sliding quick adjustment (a stretcher sling cut down) and a hook at either end to engage the sides of the top of the theatre table. One of these placed over the knees and another the

FIG. 5.

chest and elbows of a patient saves one and often two orderlies during the induction of anaesthesia.

All these have been tried in casualty clearing station work during the last ten months and proved most useful, as well as saving labour during "rush" work. They are light and easily made; a coating of white enamel improves their cleanliness. The chest rest can be made with double hinges for ease of packing. The operating table referred to is the standard W.D. pattern.

W. F. BENSTED-SMITH, Captain R.A.M.C. (T.F.).

London, E.C.

DERMATITIS FROM HANDLING EXPLOSIVES.

CASES similar to those described by Dr. Sequeira in the *BRITISH MEDICAL JOURNAL* of June 30th have been observed in France amongst soldiers.

About a year ago a series of explosions took place in an ammunition dump. A considerable number of shells were removed in time and transported to a place of safety. These were, however, covered with a yellowish powder from the explosion of other shells in the vicinity. Several days later a number of men were admitted to hospital from a labour battalion engaged in handling these "yellow" shells.

The first case admitted showed a large number of deeply seated vesicles upon the hands, distributed mainly on the palms and between the fingers, intensely irritable, and resembling closely a severe cheiropompholyx. The palms of the hands were of a bright yellow colour, and a local irritant was at once suggested. Against this, however, were the facts (1) that the man had been employed on unloading shells for several months, (2) that he had been handling the "yellow" shells for over a week—a period considerably longer than that required for most irritants to produce dermatitis, (3) that though most of his co-workers had yellow palms no others had as yet developed any eruption, and (4) that the eruption did not extend further up the arm than the palms. On these grounds, and also that no previous case of "shell dermatitis" had been seen, the provisional diagnosis of cheiropompholyx was made.

That this was incorrect and that the irritant was certainly responsible became evident next day, when several other cases arrived from the same company, all showing a more or less similar eruption on the hands. Others followed on successive days, about a dozen in all being admitted, and in several of these there was an

eruption on the arms extending up nearly to the shoulder, apparently affecting those parts exposed when the sleeve is rolled up. In this situation the eruption was not vesicular but resembled severe seborrhoeic dermatitis.

The cases were treated in the acute stage with starch poultices, and later, when the inflammation subsided, with boric starch dusting powder, containing a small quantity of salicylic acid. The course followed closely resembled that of an ordinary pompholyx, the eruption being followed by desquamation. Some idiosyncrasy seemed to be necessary to determine the eruption, for though a whole company was engaged on the same work only a small proportion became affected.

Subjects of the seborrhoeic diathesis seem particularly susceptible to the action of irritants. The dermatitis observed by Dr. Sequeira, and noted also in France, seems to be closely allied to the variety which occurs amongst munition workers from the handling of explosives.

W. D. D. SMALL,
Captain R.A.M.C. (T.C.).

On July 3rd a man was told off to clean out a cistern into which had fallen a bomb from an aeroplane. He noticed a yellow powder in the water. His hands were immediately stained yellow and his feet were wet.

Ten days later a vesicular rash appeared on the skin of the palm and the dorsum of the hands and between the fingers. The vesicles were very small and deeply situated in the true skin. There was much redness, accompanied by the feeling of heat and itching. A similar rash appeared on both feet.

The rash lasted some thirteen days, after which the skin over the affected areas peeled off in large flakes. The itching was much worse during this stage. The patient was treated with calamine lotion.

Felixstowe.

P. L. GIUSEPPI, M.D. Lord., F.R.C.S.

THE SPHYGMOMANOMETER IN GENERAL PRACTICE.

As the stethoscope and clinical thermometer are the constant companions of the general practitioner, so should the sphygmomanometer be also. If used regularly and careful records kept, it will prove invaluable not only as an aid in diagnosis, but also in prognosis and treatment. Indeed, as proof of its worth, many of the life assurance companies ask for a blood pressure reading. For some I have used a Tycos apparatus, which is portable and reliable, and its use has not only been a scientific pleasure, but an invaluable help in cardiac, renal, and pulmonary cases. It is to its value in tuberculosis cases especially that I wish to draw attention in this note; I have found hypotension a constant feature, and the early diagnosis of phthisis has been possible before any appreciable signs or symptoms have developed, or the bacilli have been found in the sputum. Indeed, any case exhibiting a persistently low blood pressure, with a small pulse ratio, should lead one to suspect tuberculosis. Not only is early diagnosis possible, but the blood pressure reading enables one to watch the progress of the case. If the maximal (systolic) pressure increase accompanied an improved pulse ratio we know the case is progressing satisfactorily; if, on the contrary, a decrease is noted, the prognosis is invariably bad. In short, it may be said that all conditions having a sustained pressure of 100 mm. or lower, or over 150 mm., must be regarded as pathological.

Blood pressure depends on four factors—cardiac power, peripheral resistance, elasticity of the walls of the vessels, and the quantity of blood in the circulatory system. For correct estimation the systolic, diastolic, and pulse ratio readings are of equal importance.

To discuss the various meanings of blood pressure readings generally is not only a task beyond my power but beyond the scope of this note, which is intended to draw attention to the immense help the sphygmomanometer can give when regularly used in practice, and especially as an aid in the early diagnosis of phthisis, for it is now universally admitted that it is only in the early cases we can hope to achieve any measure of success in treatment.

By way of illustration I may quote two recent cases.

A young man passed as fit for general service came to me complaining of hoarseness and a slight cough. His temperature was raised, but he had no definite lung signs. The systolic

blood pressure was only 90 mm. with a diminished pulse ratio. I at once suspected tuberculosis, and when the sputum could be had it proved to be positive. He died soon after. There was no family history; it was a case of direct infection from tuberculous meat; he was a butcher, and, like many others in his trade, held a knife in his mouth while dressing a tuberculous calf.

The second case was a young girl of 16 with a bad family history who was ill for three weeks with vague stomach symptoms. Her blood pressure readings showed marked hypotension. A week later cough developed and the sputum was examined, but reported negative. The following day some more sputum was sent to Dr. R. Solly, of Exeter, who reported tubercle positive.

In these two cases, then, diagnosis was possible before definite signs appeared.

In conclusion I should like to add that as variations may occur in normal conditions under abnormal circumstances, repeated readings are necessary and careful records must be kept.

Cheriton Fitzpaine, Devon.

DAVID H. VICKERY,
Late Surgeon R.N.

Rebrielus.

HEALTH AND THE STATE.

DR. BREND is a clear-headed, able writer, and although we may not agree with all his conclusions he deserves a careful hearing. In his recent book, *Health and the State*,¹ he examines critically the existing public health services, the measures now in force, and the methods by which they are administered. Dr. Brend finds waste and inefficiency, and the main object of his book is to demonstrate the need for complete reorganization of the public health services. He suggests three main reasons for the failure to apply the large mass of knowledge available as to the means for the prevention and cure of disease: (1) vested interests, (2) complex administration, (3) ignorant legislation. About the first there is not much to be said, the facts are well known; the second is fully discussed by Dr. Brend in various parts of his book. From the Government departments, tainted with official bias, right away down to the smallest local authority, he finds overlapping and lack of co-ordination. With regard to ignorant legislation, he has many hard things to say about our rulers. His main thesis here is that most of the past endeavours made by the community to reduce or stamp out disease have failed, and wrong views have been spread throughout the people, because the problems involved have not been sufficiently investigated. "Wherever effort to improve public health has failed, it has not been the fault of medical science, but of legislators and administrators who have misunderstood that science, or have failed to appreciate the difficulties and conditions under which they proposed to apply its teachings."

In the chapter on the causes of infant mortality, which is a reprint from a publication by the Medical Research Committee, it is contended that post-natal factors beyond the mother's control are far more potent forces than either pre-natal conditions or maternal ignorance and neglect. The author's view as to the importance of environment finds fuller expression in the chapter on public health, land, and housing. This has for its text the assertion that man is biologically not adapted to life in towns. True measures of reform, according to this dogma, should not tinker with curative and palliative measures, but should attack disease-producing conditions, in particular the deadly habit of urbanization. "The land question lies at the bottom of nearly all the forces which make for ill health, whether they be rural depopulation, holding up of suburban land, continuance of slums, or insufficient housing."

The present position of medical treatment among the working classes is discussed in two long chapters, with special reference to the operation of medical benefit under the National Insurance Act. The author holds that the public health aspects of this measure have been quite lost sight of, and that the whole complex system set up under it has been of little benefit to the health of insured persons; the drug fetish has been perpetuated; the standard of treatment among the insured class is no

better than that which prevailed before the Act, and the elaborate records give doctors much trouble, and are of no scientific value. In short, he thinks the panel system unsound throughout. Enormous powers have been given to the Insurance Commissioners, resulting in an extreme degree of centralization and complexity of administration, while the local Insurance Committees, from which much was expected, are impotent and futile bodies merely engaged with minor administrative details. The Insurance Act, the author tells us, was the most ambitious piece of public health legislation ever attempted; but, like nearly all others, it suffered from complete absence of scientific medical inspiration, and so was an amateurish affair from the start. We seem to remember a time when Dr. Brend was not quite such a severe critic of this measure.

The author is naturally in favour of the setting up of a Ministry of Health to put things straight. He has his own plan for reorganizing the public health services both central and local. The only authority for which he has a good word is the Registrar-General's office; it is not concerned with administration, and it carries out the most important public health research in the country: this, then, he thinks, should be the nucleus of the new department. The great function of a Ministry of Health, according to Dr. Brend, should be research into public health questions, especially of a sociological kind, with a view to the application of scientific knowledge to the needs of the community. An independent and unbiassed body of skilled scientists should investigate the causes and distribution of disease, and consider and advise on all legislative public health proposals. The functions of this ministry would thus be investigational, consultative, and advisory, rather than executive. Existing Government departments concerned with health do not, in the author's view, need uniting so much as co-ordinating; some rearrangement is necessary, but co-ordination is the principal need, and this mainly in their scientific and statistical work. Administration should be simplified by decentralizing the services. For instance, the Insurance Commission should remain a merely financial body responsible for central administration, and the machinery of medical and sanatorium benefit should be taken out of the Insurance Act and merged into local medical services no longer applying solely to insured persons. Thus the greater part of health administration would pass into the hands of local bodies furnished with increased powers and combining for all health purposes into single local health authorities. Dr. Brend thinks that the best plan would be to appoint the ministry first on the lines he suggests, and authorize it to inquire into the whole system of public health administration, and recommend what further changes are desired.

KUT AND AFTER.

UNDER this heading two recent books may be noticed. The scope of the one is sufficiently indicated by its title, *Besieged in Kut—and After*,² but a great deal the most interesting part of it is the story of the siege. Its author, Major CHARLES H. BARBER, I.M.S., seems to have been with his hospital at Basra for nearly a year before he went up to Kut in October, 1915, with as much of the equipment and as many of the personnel as a small steamer could carry; the remainder got up by instalments in time to be established, along with another of 500 beds, a short time before the British retreat from Ctesiphon. The two hospitals would seem to have received temporarily some five-sixths of the wounded from that action, probably nearly 4,000 men, but contrived to pass most of them on before the investment was complete. When that happened the hospitals had to be moved from their huts outside the town into the bazaars on the river bank, but this site, though less exposed, was by no means safe from shells, and great havoc was wrought one night by a bomb dropped from an aeroplane plumb in the middle of the British hospital in the upper part of the bazaar. It is a sad story—the alternations of hope and despondency as the relief force tried and tried again and failed. Each failure was marked by a reduction of rations, until to the pangs of hunger was added scurvy, which handicapped the surgeons, making them refrain

¹ *Health and the State*. By W. A. Brend, M.A. Camb., M.D. (State Medicine), B.Sc. Lond. London: Constable and Co., Ltd. 1917. (Demy 8vo. pp. 361. 10s. 6d. net.)

² *Besieged in Kut—and After*. By Major Charles H. Barber, I.M.S. Illustrations and Maps. Edinburgh and London: William Blackwood and Sons. 1917. (Cr. 8vo. pp. 344. 5s. net.)

from operations that would otherwise have been beneficial. As to this, readers may recall the report of a medical meeting at Kut on April 1st, 1916, published in our columns of January 6th, 1917. The disease seems to have been noticed first early in February and to have increased rapidly until about the middle of March. Then the warmer weather stimulated growth, and grass and weeds were collected and cooked as spinach—a nauseous mess, but effective as a cure and prophylactic—and vegetables sown early began to yield crops. Perhaps the most vivid impression of the gradual descent from shortage of food to absolute want is given by the story of the flour mill. Machinery was found near the fort, the most advanced point in the semicircle of the defence, and brought into the town and put together; millstones which were wanting were dropped by aeroplanes, hidden stores of grain were rooted out and the mill began to grind merrily. But a couple of months later—early in April—Major Barber relates how, making his way by a back lane through the town, he came on the flour mill. "It was still . . . like everything else it had the air of having finished. It had done its job." The book is illustrated by drawings, photographs and sketch maps, and contains Townshend's official announcements to his troops, which it was well to preserve. This story of the siege will live by reason of its directness and vivid touches of realism.

The *Message from Mesopotamia*^{*} which Sir ARTHUR LAWLEY brings after spending last February and March there, is that though the campaigning on the Tigris plain is fraught with difficulty and danger owing to the physical conditions, "the steps which have now at last been taken to minimize the risks and ensure the well-being of our men seem to me to be wise and adequate." He went to Mesopotamia as the representative of the British Red Cross and the Order of St. John, and visited all the principal military posts from the base at Basra to Baghdad, which he entered with the flotilla on the day after the fight for the DIALA crossing ended. He saw the evacuation of the wounded from that action, and speaks highly of the good work done by the Red Cross motor launches. The wounded had to be carried in ambulances or carts over a bad stretch of country (some eight miles) to the river bank, but the launches took them thence to the field ambulances below. An advanced Red Cross dépôt was quickly established in a good house in Baghdad. With regard to stores, the work of the Red Cross has been to supplement the official equipment by the provision of extra comforts to hospitals and hospital ships; in future it is proposed to rely more and more on the Indian Branch of the Joint Committee of which Sir Pardey Lukis is chairman; he, says Sir Arthur Lawley, is "a tower of strength," never failing to meet "endless demands on him for supplies of every kind." The most novel work has been the provision and maintenance of motor launches; in an amphibious campaign such as this launches of various sizes and adapted to serve various purposes can be of the utmost use, but Sir Arthur states that when he left the only launches available for use by the medical service were those supplied by the Indian Branch of the Joint War Committee and the Order of St. John. This does not seem quite satisfactory, for it suggests that even yet the principle that the medical service is an essential part of any army, to be furnished, without question and as a matter of routine, with suitable transport on an adequate scale, is not fully understood and acted upon. After enumerating, in a concluding chapter headed "All's well," the evils of a summer campaign in Mesopotamia—the evils of heat, of flies, mosquitos, and sandflies, of fever and dysentery, of dust, thirst, and ennui, which, he says, our army to-day will look in the face undaunted and undismayed, Sir Arthur Lawley adds the significant sentence, "the clouds of doubt and distrust which twelve months ago darkened the horizon and quenched the spirit of our soldiers have been swept away. The men are in great heart, they know that they are going to win through. They know that their leaders will look carefully to their well-being." Is it good generalship to let the spirit of your men be quenched because they know that proper provision has not been made for them if wounded or sick, as must happen? Such

lapses are excused on the ground of military exigencies. But is not the care of the sick and wounded from a force one of the military exigencies for which a skilled commander and a competent military administration always provides?

NOTES ON BOOKS.

THE eleventh edition of the late Professor SIMON'S *Manual of Chemistry*,⁴ revised by Professor BASE of Baltimore, is in many respects an improvement on the tenth, which was reviewed in the *BRITISH MEDICAL JOURNAL* of February 1st, 1913 (p. 227). The book is now devoted entirely to chemistry, inorganic and organic; the section given in previous editions to physiological chemistry has been omitted, with the exception of the chapter on the proteins. The first fifty pages deal with chemical physics; inorganic chemistry is discussed in the next three hundred pages, and then follows a short section on analytical chemistry. Organic chemistry is described in the following two hundred pages, and there are four appendices, of which two are given to the spectroscopy and the polarimeter. The reviser is to be congratulated upon the success with which he has carried out his work. The book has long been an established favourite in America, used by students of chemistry as well as by students of medicine. It is written in a somewhat academic style; but has the virtues of fullness and trustworthiness. The preface reveals an interesting, and for practical purposes wholly undesirable, instance of the confusion introduced into the terminology of standard measures by a pedantic adherence to accuracy. Professor Base writes: "The U.S. Bureau of Standards, the U.S.P. and Br.P., U.S. publications, and a number of authors, have adopted the term milliliter (abbreviated mil. or ml.) in place of cubic centimeter (c.c.), inasmuch as the liter, as now fixed, is 0.027 c.c. larger than one thousand cubic centimeters." Thus 1.0 mil. = 1.000027 c.c.; Professor Base has not adopted the "milliliter" in this volume. The book may be warmly commended to those for whom it is intended.

Miss MARGARET E. BJÖRKEGREN'S *Handbook of Anatomy for Students of Massage*⁵ contains all that it is necessary for them to know on this subject, with illustrations from Buchanan's *Manual of Anatomy*. The chapter on surface markings in this second edition has been enlarged and other alterations and additions made which should increase the value of the book as a practical manual.

⁴ *Manual of Chemistry*. By W. Simon, Ph.D., M.D., and Daniel Base, Ph.D. Eleventh edition, thoroughly revised. London: Baillière, Tindall, and Cox. 1917. (Roy. 8vo, pp. xvi + 648; 55 illustrations, 7 coloured plates. 13s. net.)

⁵ *Handbook of Anatomy for Students of Massage*. By Margaret E. Björkgren. Second edition. London: Baillière, Tindall, and Cox. 1917. (Demy 8vo, pp. x + 233; 73 figures. 5s. net.)

MEDICAL AND SURGICAL APPLIANCES.

Apparatus for Treatment of Dislocation of the Acromial End of the Clavicle.

MR. HERBERT H. BROWN, M.D., F.R.C.S. (Ipswich), writes: Dislocation of the acromial end of the clavicle is not a very common injury. It can only take place if there is rupture of the strong conoid and trapezoid ligaments attaching the clavicle to the base of the coracoid process. While easily reduced, it is difficult to keep the clavicle in contact with the acromion; any contraction of the trapezius muscle raises the bone. Some years ago I devised the simple apparatus shown; it was made for me locally, and can now be supplied by Messrs. Meyer and Meltzer. A is an oblong pad, which rests upon the clavicle near the acromion. The upper surface is of stout leather, and underneath is a soft pad covered with chamois leather. Between the two slides a leather strap attached to a bucket splint (B) of leather, supporting the forearm and elbow, by buckles in front and behind the arm. From the inner angle of the pad A a strap passes to a soft pad (C), which rests in the opposite axilla. This strap can be adjusted by a buckle. In adjusting the apparatus the straps between the clavicle pad A and the splint B should be drawn tight so as to prevent any displacement of the clavicle upwards. The strap attached to the pad C prevents the pad A from slipping off the shoulder. For the first fortnight the apparatus may be worn next the skin, afterwards outside the shirt. In the cases in which I have used it, it has been entirely satisfactory.

^{*} *A Message from Mesopotamia*. By the Hon. Sir Arthur Lawley, G.C.S.I., G.C.I.F. London, New York, and Toronto: Hodder and Stoughton. 1917. (Small 8vo, pp. 143. 2s. 6d. net.) The author's profits will be given to the Prisoners of War Fund.

British Medical Journal.

SATURDAY, AUGUST 4TH, 1917.

WOUNDS OF THE CHEST.

A COUPLE of months ago, in a note appended to the paper by Sir Anthony Bowlby and Colonel Cuthbert Wallace on the development of British surgery at the front, Colonel Sir Wilmot Herringham gave an account of penetrating wounds of the chest observed at a casualty clearing station. This week we are able to publish a paper by Colonel Sir John Rose Bradford on gunshot injuries of the chest, dealing especially with the conditions observed at the base hospitals. Sir Wilmot Herringham told us that in all but fourteen out of a consecutive series of 211 cases seen at casualty clearing stations there were signs of haemothorax, and Sir John Rose Bradford's paper is largely concerned with the treatment of this condition as observed later on. Sir Wilmot Herringham made a passing reference to a new method of treatment of penetrating wounds with retention of the missile, introduced towards the end of 1916. On the second day after the injury ribs were resected or a costal flap turned back, the pleura opened, the missile removed, the pleura thoroughly washed out, and the whole wound carefully closed. The number of cases so treated within his experience was limited, but the results observed had been favourable. The treatment of chest wounds until recently may be summed up by the statement that it has been in the main expectant, coupled with free drainage as soon as bacteriological evidence of pyopneumothorax was found; this, if it occurred, usually came on within ten days.

In the early summer of 1916 there was a move on the British side towards surgical treatment, but it was interrupted by the long offensive on the Somme front. There was also in the same year a similar movement on the French side under the lead of Duval, who showed that the lung could be freely exposed and handled without producing shock or interfering seriously with respiration, and that in cases of serious haemorrhage life could often be saved by direct attack on the bleeding parts and suture of the lung tissue. He argued that such operations, besides arresting haemorrhage, tended to prevent after-complications, and suggested that the lung was as self-protective as the peritoneum, but could not withstand constant exposure, through a breach of its surface, to the influence of an infected pleural cavity. Proceeding from this, he argued that all chest wounds in which a foreign body was buried might rightly be treated like, say, thigh wounds, by prophylactic or surgical cleansing operations.

Duval began to give expression to his views in the late autumn of 1916, and about the same date a consideration of the possibilities of chest surgery was resumed on the British side. At first the operations were of a tentative nature, but the results were of such a kind as to cause the pendulum of opinion to swing rapidly in favour of abandoning expectant treatment as the routine procedure in front line units. It has now swung again to the perpendicular, and the present view seems to be, first, that in the comparatively rare cases in which patients suffering from severe haemorrhage survive to reach an operating station life may occasionally be saved by operative interference. Secondly, that prophylactic operations

are legitimate and desirable in two classes of cases in which grave infection is otherwise certain to occur: those in which so many ribs are destroyed that the lung is certain to be infected from without, and those in which there is a large opening in the chest wall and the contents of the pleural cavity are churned at every movement of a not entirely collapsed lung. Thirdly, that operation for the removal of a foreign body, which may very possibly cause infection, but will not certainly do so, is also legitimate, subject to two provisos—namely, that it is known to be large and can be localized precisely by x rays, and that the operation can be undertaken in what may be called the pre-sepsis stage—in other words, within the first twenty-four hours or so after receipt of the wound. Fourthly, that search for small fragments is illegitimate even if the foregoing provisos are met, for they do not always cause infection, and, when they do, early treatment of the resulting pyopneumothorax by free drainage gives very good results.

It appears, in short, that the treatment of chest wounds is undergoing, if it has not already completed, much the same evolution as the treatment of abdominal wounds underwent. In the early days the treatment of abdominal wounds was for the most part expectant, and those who considered that it might be anything else with advantage had to admit that operations could scarcely be advised in existing conditions. When, however, with the continuance of trench warfare the casualty clearing stations gradually changed their character and were more fully equipped, operations on the abdomen began to be undertaken with encouraging results. It was clear, however, from the beginning that success was largely dependent on the earliness with which these operations were undertaken, and the first formal attempt to meet this proviso and to make a definite feature of abdominal surgery was spoilt by the military circumstances in which it necessarily took place. This was Loos of 1915. In order to secure the cases early the abdominal operating station was placed close to the ordinary field ambulances, but the casualties of all kinds were so heavy that the abdominal work was quickly overwhelmed. The next formal endeavour was made in quiet times, the operating stations being placed fairly close to the line but off the main lines of traffic, and arrangements were made for bringing cases straight down to them. In this and other ways the possibilities of abdominal surgery were soon established, with the result that for at least a year abdominal surgery has been an habitual and very successful feature of front line casualty clearing station work.

The problem of the treatment of abdominal cases having been solved, that of chest wounds was taken in hand, with the results above indicated. It is to be noted, however, that so far as the base hospitals are concerned no change is likely or desirable. In the first stage of the war the general impression was to the effect that chest wounds were curiously benign, and it has been borne out by experience so far as bullet wounds are concerned. If these do not cause death from haemorrhage, recovery is usually rapid and complete. Nowadays, however, the majority of wounds are due to shell fragments, and these are more liable to provoke sepsis. Nevertheless, it is found at the base hospitals that even when infection occurs or the recovery is otherwise not uninterrupted, excellent results may be expected, even in very severe infections, if the principles of treatment recently so well set forth in full in the *BRITISH MEDICAL JOURNAL* by Lieut.-Colonel Elliott and Captain Henry¹ are duly

¹ Infection of Haemothorax by Anaerobic Gas-producing Bacilli. *BRITISH MEDICAL JOURNAL*, March 31st and April 7th, 1917.

observed. Not only do chest wounds, as seen at the bases, return quite a low mortality, but on their arrival they have usually passed the stage when operation can be safely undertaken, unless free drainage is to be regarded in that light.

The mortality from chest wounds, however, is not fully represented by the experience of the base hospitals. In many cases death from haemorrhage occurs at once, and among those that survive to reach the casualty clearing stations and advanced operating stations a considerable proportion die within a very short time either from the continuance of haemorrhage or the onset of fulminant sepsis. There now appears reason to believe that a good many of these formerly fatal cases can be saved by surgical interference. If this conception prove well founded, thoracic surgery, like abdominal surgery, will be a bright spot in the history of the war. Both have been rendered possible by the wise policy of the Director-General in France and his advisers of developing casualty clearing stations to such a degree that they are now hospitals of the very best type, and in every sense of the term.

Two points of general interest emerge from what has been said, and from the underlying facts. Lung tissue does not resent handling, suturing, and other surgical procedures. Formerly regarded as intangible, it has been shown to be as tangible with safety as another structure which was formerly regarded as being too dangerous to touch—namely, the peritoneum. The other point is that, though operations on the chest and its contents are not entirely novel, it has hitherto been supposed that their performance is only possible with the assistance of complicated arrangements in the way of compressed-air chambers and other devices for maintaining equality of pressure. It is now seen that all these things are superfluous, and that a lung can be fully exposed with safety and success in any ordinary operating room, and without the assistance of any special devices. It is also clear that chest surgery demands no unusual technical ability on the part of the operator, but that what is essential is judgement to decide between the cases that should be subjected to operation and those in which it should be withheld. Chest work, in short, cannot be undertaken successfully except by the co-operation of sound physicians, skilled surgeons, and good radiologists.

THE ANNUAL REPRESENTATIVE MEETING.

THE annual meeting of the Representative Body was held in London at the close of last week. The attendance was good for the end of the third year of the war, and close interest was manifested throughout. In spite of a long programme the business was disposed of within the two days. Wider discussion at the present moment of certain very large questions would scarcely have repaid the expenditure of time and energy involved in prolonging the session into a third day. The publication of a report of the proceedings is commenced in the SUPPLEMENT this week, but exigencies of space compel us to hold over the remainder until next week. We shall not attempt here a running summary of resolutions and debates covering almost the whole field of medical politics, but certain outstanding features of the meeting may now be mentioned.

The troubled times in which we live justify special reference to the Treasurer's financial statement. The paragraphs of the annual report of Council relating to finance have been before the members of the

Association since May 5th, and in moving their approval, Dr. Haslip went into the factors which have mainly affected the finances of the Association since the outbreak of war. Notwithstanding grave difficulties, it has been possible, through the increased revenue from subscriptions, and by means of drastic economies in the production of the JOURNAL, to reduce indebtedness on account of loans to much less than a quarter of the amount outstanding at the close of 1913. Anxious days are ahead, but this restoration of financial equilibrium in the midst of a period of great stress is a matter for congratulation. Whilst on this subject we may remark that the Treasurer's figures throw light on editorial difficulties in war time and explain the need for rigid selection and compression of everything submitted for publication.

A noteworthy aspect of the Representative Meeting was the praise accorded to the work of the Central Medical War Committee. The manner in which the statements of its Chairman, Dr. Verrall, were received and the tone of the Representative Body throughout their discussion, made it clear that the unremitting efforts of the Committee on behalf of the civil population, the army, and the medical profession are appreciated by the body of the profession. Complete approval was expressed of the firm attitude taken up by the Central Medical War Committee, and the Committee of Reference, at the end of April last, when the War Office made the unfortunate blunder of calling up all medical men under 41 without reference to the statutory professional committees. It is evident that the strong and prompt action then taken did more than was recognized at the time to establish the committees firmly in the confidence of medical practitioners up and down the country. Representatives who came with amendments questioning once more the payment out of Association funds of the expenses of the Central Medical War Committee disclaimed any intention of criticizing the work of the Committee, and the general view of the meeting, reinforced again by legal opinion, was that this work amply justifies the disbursement of Association money, although non-members profit by it equally with members. Again, upon the grave question of mobilization of the medical profession, the Representative Body, after hearing both sides, decided to associate itself with the resolution passed in December last by the Central Medical War Committee, with the proviso that any such control of the liberties of medical men in advance of other sections of the community, if and when needed for national security, must be carried out under the direction of accredited representatives of the profession, by which was understood the statutory professional committees.

The cognate question of the supply of doctors for the army was also raised during the meeting, but any tendency towards a discursive ventilation of specific grievances and anomalies was wisely held in check. The very widespread feeling that the War Office is not making the best use of the medical men supplied to it, and that the combing-out process has gone dangerously far already, found expression in a resolution, passed without dissentient vote, which will strengthen the hands of the War Committees in future dealings with the army authorities. In the matter of the reconstitution of medical recruiting boards, the Representative Body gave general approval to the steps already taken to watch over professional interests by the special committee of the Council of the Association, and by the conference on July 25th between the Central Medical War Committee and the Committee of Reference. As the outcome of these votes of confidence, the professional bodies charged with the national duty of selecting

civilian doctors for the army, and of safeguarding the civil population and the medical profession, will feel encouraged to continue spending themselves upon this task, knowing that they have behind them the support of the profession at large.

The recommendations of the Council with regard to a Ministry of Health were introduced by Dr. Garstang, who explained the origin of the scheme. From various amendments sent up by Divisions it was clear that misunderstandings had arisen as to the reason for the action taken in this matter by the Council in advance of a mandate from the constituencies. The explanations given by Dr. Macdonald and Dr. Brackenbury satisfied the meeting that the Council, if it had not at once moved in the matter, would have failed in its duty. The Representative Body, when the position was fully revealed to it, endorsed the action of the Council, and approved generally the outline scheme put forward. The meeting eschewed a rambling discussion of details, and showed its renewed confidence by entrusting to the Council further consideration of the matter and the duty of representing the scheme to the Government. The oversight by which the reasons prompting the Council to take rapid action were not fully explained in the report of Council has thus been corrected in the fullest possible manner, and misapprehensions have been removed. Whatever may be the merits, or demerits, of the scheme proposed, the idea that it is a State medical service in disguise is now recognized to be altogether mistaken—in fact the exact opposite of the truth. Here it should be noted that the Representative Body at a later stage in the proceedings, when national health insurance matters were under consideration, passed resolutions to the effect that medical treatment of the industrial and poorer classes should not be carried out by a whole-time salaried State medical service, but by a modified and improved insurance scheme.

RECRUITING.

THERE is no published evidence that any progress has been made, since we referred to the matter last week, with the scheme for handing over the organization of recruiting for the army to a civilian body. The Secretary of State for War distinctly declined to commit himself to the suggestion of the Select Committee that the work should be undertaken by the Local Government Board, and there have been several suggestions that the National Service Department, which seems to be out of work, would be willing to undertake it. There is also a suggestion that the recruiting department should be independent of any other; and, finally, a suggestion that the advice of the Select Committee should be disregarded and the department retained as a section of the War Office, but reorganized with a larger civilian element in control and administration. Any civilian recruiting authority will be faced with an extremely difficult problem, and on the medical side it will only be possible to solve it completely by making the fullest possible use of existing medical organizations. As was pointed out last week, the work to be done has two aspects—the calling up of men for medical examination, and the medical examination itself, which must involve some primary classification. The first aspect has nothing to do with the medical profession, but it was the mistakes made by inexperienced recruiting officers in calling up for medical examination many men who were obviously unfit, and too many men for examination each day, so that they had to come day after day, that gave most of the substance to the agitation. The two points made by Lord Derby were that before any man came under

the authority of the military a civilian body should ascertain whether he could be spared from his civilian employment, and whether he were fit for any one of the various categories of service the army requires. The first point is not a medical question, the second is, but it raises military considerations. The chief difficulty of the medical profession at the beginning was that all the conditions were new; the medical examiners had no experience of the kind of work which recruits would be called upon to undertake in the various branches of the army. The old idea, that only men absolutely fit in every way could be utilized by the army, was given up long ago, as it was soon seen that on such a basis an adequate number of men would not be obtained, while numerous men would be rejected who could do useful work in the army in categories other than the fighting line. We believe that when Lord Derby's second point—that is to say, whether a man is fit for any of the various categories of service required by the army—is carefully considered, it will be seen that the presence of medical men having military experience on medical examining boards is a necessity. The mistake, it seems to us, has been that the presidents of these boards have been in so many instances retired regular medical officers unacquainted with civil conditions, and that sufficient use has not been made of Territorial medical officers and those who have held temporary commissions and gained experience during the last two or three years with the armies in the field. Another point is that the army authorities will have to arrange that when a recruit has been classified by a civilian board, he shall not after he has entered the army be put into a different category except at the direction of a properly constituted military medical board. On the whole it is fair to say, however, that the situation had been gradually improving, and would probably have been satisfactory by this time but for the interference of the Select Committee.

UNQUALIFIED PRACTICE OF DENTISTRY.

THE Departmental Committee appointed by the Lord President of the Council to investigate the extent and gravity of the evils connected with the practice of dentistry and dental surgery by persons not qualified under the Dentists Act has held a preliminary meeting. The members are: The Right Hon. Francis Acland, M.P. (Chairman), Sir Almeric FitzRoy (Clerk of the Council), Sir Arthur Newsholme (Medical Officer of the Local Government Board), Sir George Newman (Chief Medical Officer of the Board of Education), Lord Knutsford, Mr. C. S. Tomes, F.R.S., Mr. W. H. Dolamore (President of the British Dental Association), and Mr. G. P. Blizard. Mr. F. N. O. Jerman, staff clerk of the Local Government Board, is acting as secretary. The subjects into which the committee are directed to inquire are: (1) The causes of the present inadequate supply of qualified dentists and dental surgeons. (2) The expediency of legislation prohibiting in the United Kingdom the practice of dentistry and dental surgery by unqualified persons; and, in the event of such legislation being deemed expedient, the conditions under which certain classes of unqualified persons at present engaged in the practice of dentistry might be permitted to continue in practice by the institution of a special roll for the purpose. (3) The practicability, without impairing the existing guarantees for the efficient practice of dentistry, of (a) modifying the course of study and examination prescribed for dental qualifications; (b) reducing the time occupied; (c) diminishing the cost of training dental students.

LORD RHONDDA AND A MINISTRY OF HEALTH.

LORD RHONDDA, in presiding on July 30th over a meeting of the National Baby Week Council, expressed regret at leaving the Local Government Board before he had completed the work which he had undertaken there. He repeated his public statement that before accepting the

post of Food Controller he had obtained a pledge from the Prime Minister that this unfinished work should not be thrown away. Relying on this promise, Lord Rhondda expressed his belief that before long, probably early next session, a bill would be introduced for the setting up of a Ministry of Health. He had no doubt that the pledge would be fulfilled, but those interested in the question must go to work to satisfy the Government that the overwhelming mass of public opinion was in favour of such a Ministry. The only opposition of which he was aware came from those claiming to represent certain approved societies; but he had received a very satisfactory letter from the Executive Council of the Association of Approved Societies dissociating themselves from any opposition to the proposals of the Government and forwarding a resolution in favour of the establishment of a Ministry of Health. This resolution, passed by the executive on July 18th, expressed the view that it is desirable in the interests of the health of the community, uninsured as well as insured, that immediate steps should be taken to set up a Ministry of Health, which would take over the principal health services, including the care of lunatics, feeble-minded, and inebriates; the medical profession, and midwives; the medical care of school children, and the administration of medical and sanatorium benefits; that the functions of the Insurance Commission should form an integral part of the work of this Ministry, and that approved societies should continue to administer sickness, disablement, and maternity benefits under the direction of the Minister of Health. Lord Rhondda expressed his pleasure at receiving this letter, but he was not fully satisfied that there were not some vested interests opposed to the proposal. In this matter the Government should be guided not by vested interests but by public opinion. In reply to a question as to the scope of the proposed bill, he said that the aim was to co-ordinate the activities of the various branches of Government departments now dealing with public health matters. The present overlapping of departments made for inefficiency, friction, and lack of economy. Regarding this bill as an urgent war measure, he had made it as short and as little complicated as possible. He had been informed on good authority that a thousand infant lives a week were lost that might be saved, and one of the means he proposed to remedy this was to co-ordinate the health functions of different departments of State; beyond this he had not proposed to go in the first instance. When the health activities of these various departments had been brought together under one head the way would be open for immediately improving the health of the country. A resolution in favour of the establishment of a Ministry of Health was unanimously carried by the National Baby Week Council, on the motion of Mr. E. B. Turner, seconded by Dr. Eric Pritchard. Two days later, in the House of Commons, Mr. Bonar Law, replying to questions from Sir William Collins and Major Chapple, said that the Government had not decided to establish a Ministry of Health, nor did they think it advantageous to set up a commission to consolidate the existing laws affecting questions of public health before the establishment of such a Ministry had been decided upon.

HOUSING.

The President of the Local Government Board has issued a circular to local authorities, asking them to state whether there is or is not need for further housing for the working classes in their area, and whether they desire financial assistance from the Treasury. It is recognized that for some time after the war many of the difficulties which have brought the building of such houses almost to a standstill will continue to prevail, and that throughout the period of the war there will be an increasing arrear of building to be subsequently overtaken. It is considered that the provision of such houses is one of the most

pressing of post-war problems for which immediate preparation should be made, and it is realized that private enterprise, to which was due approximately 95 per cent. of such building prior to the war, will be unable to grapple successfully and speedily with this arrear. The Government has therefore come to the conclusion that for the year, immediately following the war it will be necessary to rely far more than in the past upon local authorities to provide the houses required, with their road, water, and drainage accompaniments. The War Cabinet has approved the suggestion to afford substantial financial assistance from public funds to those local authorities prepared to carry through without delay at the conclusion of the war a programme of housing for the working classes approved by the Local Government Board. At the same time, Mr. Hayes Fisher recognizes that the complete solution of the housing problem is not likely to be accomplished except with the co-operation of private enterprise, including that of public utility societies, and that in order to secure full advantage of their help it may be advisable for the State to offer them assistance in one or other of the directions now under the consideration of a conference sitting at the Local Government Board. It is added that it is not possible at this stage to indicate either the form which the assistance to local authorities will take or its extent, but it is assumed that it will be available only for a limited period. About the urgency of the need for improved housing conditions in the majority of large and growing towns there is no room for doubt, and a sufficient number of mistakes have been made both by the Legislature and by local authorities to afford a large experience of the errors to be avoided. There is also the question of rural housing which has difficulties of its own. Housing legislation in the past has failed to achieve the beneficent object aimed at by its promoters mainly because the magnitude of the problem has not been appreciated, and the evil has been allowed to go on growing while the Legislature debated and hesitated. There is no indication in Mr. Hayes Fisher's circular of the expenditure the War Cabinet is prepared to contemplate, but it must be very large if the evil is to be abated and its growth stopped. The committee appointed to report upon the best methods of securing economy and dispatch in the provision of dwellings for the working classes in England and Wales consists, as to the majority, of architects, engineers, and other experts, with a dilution of members of Parliament, but there is no representative of the public health service, which would be surprising were it not so much in accord with the general custom of the Local Government Board. Its chairman is Sir J. T. Walters, M.P., who is a surveyor by profession.

PROPORTION OF FAT IN MILK.

A curious case, raising a question as to the regulation with regard to the minimum amount of fat in milk, was heard on appeal in the King's Bench Division on July 26th. It appeared that the respondent was the owner of one cow, which had recently calved; on a certain morning the cow had not been fully milked, some being left in it for the calf. The case arose on the sale of half a pint of the milk of the cow which was deficient in fat to the extent of 13 per cent., the actual percentage being certified to be 2.6 instead of 3 per cent., as fixed by the Sale of Milk Regulations, 1901. Four days afterwards, when the cow was completely milked, a sample taken contained 3.9 per cent. milk fat. The justices held that the deficiency was due to the manner in which the respondent had milked his cow, but held that as the milk had been sold as it came from the cow, without abstraction or addition, it was of the nature, substance, and quality demanded by the appellant, and dismissed the case. The Court of Appeal upheld the decision of the justices, but the Lord Chief Justice, after saying that the case was covered by the decision of *Hunt v. Richardson*, which was to the effect that when the product was sold as it came from the cow it was milk,

and that being so there was no offence on its sale, added an expression of his opinion that the arguments in the case had convinced him of the desirability of fresh legislation. The authorities should determine whether it was the intention of the legislature or of the departments which had the means of introducing amending Acts of Parliament that milk should be sold to the public, as it was in this case, with an undoubted deficiency in milk fat, the result being that the farmer could retain for himself the better quality, leaving to the public the inferior. Mr. Justice Atkin, in his judgement, added the observation that as things now stood a farmer was entitled by law to give preference to his own calves over the babies of his customers. The effect of the regulation and the decisions under it is that if milk does not contain 3 per cent. of milk fat there is a presumption that something has been added or abstracted, but that presumption may be met by evidence, and if a court is satisfied that it has been so met, then it cannot find that an offence has been committed.

PHARYNGITIS ARTEFACTA.

A CORRESPONDENT who has been reading the articles and the *EPITOME* on malingering published last week, calls our attention to a most extraordinary case of self-inflicted ulceration of the throat, reported to the Clinical Society of London in January, 1895. The patient was an unmarried lady, aged 36, who stated that she had been for four years suffering from an almost constant ulcerated sore throat, without difficulty in breathing or swallowing or any change in the voice. On examination it was seen that the mucous membrane of the soft palate, the uvula, the arches of the palate, and the tonsils, were affected in part by apparently submucous whitish infiltration, and in part by ulceration; in other parts the mucous membrane was bright red, in others denuded of epithelium, in others whitish shreds were seen, in others there were patches looking like diphtherial false membranes, and in others like the pricked and collapsed skins of blisters; other patches again were yellowish and even brownish in colour, as though strong nitric acid had been applied to them. Though syphilis and pemphigus suggested themselves, no definite idea could be formed as to the real nature of the disease, diphtheria even in its chronic form being excluded by the long duration. It was noted that the lesions terminated abruptly; neither in the nasopharyngeal nor in the oesophageal cavity, nor in the larynx could anything pathological be detected. When seen a fortnight later the patient considered her throat better, and though the condition on examination was similar in its general aspect the details were considerably altered. The most characteristic point was still the abrupt termination of the inflammation, with almost parallel borders both above and below, where the parts could cease to be accessible to the patient herself. A statement to the effect that the details of the appearances had much changed led the patient's mother to say that such changes frequently occurred from twelve hours to twelve hours. This confirmed the observer's conviction that the whole affection was self-inflicted. A private conversation with the mother then elicited the information that years before the patient had artificially blistered her breast and at one time blackened her face under the eyes in order to procure sympathy. It was also said that another surgeon who had been consulted had, on a second examination, become convinced that the ulceration was artificially produced. The patient denied the suggestion, though not with much indignation, and refused to go into a nursing home for observation. Six months later it was ascertained from the mother that the ulceration of the throat continued, and that the usual medical adviser of the family had also come to the independent conclusion that a sudden attack of whiteness of the throat and lips had been artificially produced, probably by silver nitrate. Protean as the morbid power of

invention of such patients is in discovering new forms of suffering for themselves in order to attract sympathy, we are not aware that either before or since has the throat been chosen as the locality for such self-inflicted injuries.

PETROL FOR MEDICAL PRACTITIONERS.

COMPLAINTS have been received from several medical practitioners, who have up to now received 60 or 70 gallons of petrol a month, that the new licences issued to them as from August 1st, limit them to 50 gallons a month—a quantity in their case quite inadequate for their professional needs. As the result of inquiries made at the Petrol Control Department, it appears that the position with regard to the petrol supply is now very acute. In consequence of the increasing shortage of petrol for civilian purposes the department is tightening up restriction all round, and medical practitioners must be prepared to go on shorter commons than ever. There is even a possibility that before very long the civilian supply of petrol will be cut off. Hitherto practitioners who proved that the allowance of 50 gallons a month was insufficient, have been able, as the result of the efforts of the British Medical Association, to obtain supplementary licences from the Petrol Department. No promise can now be obtained that the same arrangement will be continued, notwithstanding strong representations as to the need for maintaining the mobility of the remaining civilian practitioners by an adequate supply of petrol. As from August 1st, the Petrol Department will issue no new licences for more than 50 gallons a month; but it has promised to consider any case in which a practitioner can prove conclusively that the supply is inadequate; the Association will make every effort in such cases to induce the department to grant a supplementary licence.

Medical Notes in Parliament.

British Prisoners in Germany.

LORD NEWTON, who was one of the Commissioners at the conference with German Commissioners at the Hague, made a statement in the House of Lords on July 31st as to the agreements reached. All existing agreements are to be resumed as quickly as possible. The agreements as to exchanges are roughly these: (1) The exchange of civilians over 45; (2) the exchange of invalid civilians; and (3) the exchange of totally incapacitated combatants. These exchanges will, it is hoped, be resumed without any delay. Further, an agreement has been reached for more lenient schedules of disability with regard both to exchange and internment in neutral countries. Pending the conclusion of these schedules, those adopted between the French and German Governments will be utilized. Additional prisoners are to be sent to Switzerland, and to provide accommodation a certain number of men will be repatriated from Switzerland. Lord Newton was unable to give the number of men who could be accommodated in Switzerland—he could not say more than a few hundred.

Punishments are to be much diminished. For an ordinary attempt to escape the punishment would only be two weeks, and in aggravated cases would not exceed two months. Reprisals having been exercised on British prisoners of war on the alleged ground that excessive punishment had been awarded to German prisoners in Great Britain for attempting to escape, the German delegates undertook the release from punishment of all British prisoners confined under this provision. It had further been agreed that all punishments inflicted upon either civilian or military prisoners prior to August 1st shall be remitted until the conclusion of the war. As to the future it had been agreed that reprisals shall only take place after at least four weeks' notice. In cases of great urgency and importance a personal meeting will if necessary be arranged at the Hague. On complaints as to delay in the delivery of parcels the principal German delegate had explained that much of it had occurred through the necessity for an extremely strict censorship, due to the discovery in many parcels sent to prisoners of war—not necessarily British—of what were known as

instruments of *sabotage*. Both Governments had agreed to issue a notice in their own and the foreign press deprecating such practice and the German Government had undertaken, as soon as the form of words had been agreed upon, to make a large relaxation of the censorship. On complaints by the British delegates as to delay in the notification of captures the parties had agreed that captures should be notified with the least possible delay and that every prisoner should be provided with the means of communicating at once with his relatives. Minor agreements covered the treatment of youthful prisoners and the exchange of ministers of religion and of civilian doctors.

Lord Newton afterwards explained the agreement reached for the internment of a large number of prisoners, both military and civil, in Holland. The Netherlands Government had offered to put 16,000 places at the disposal of the two Governments. Of these places, 7,500 are to be allotted to invalid combatants, 6,500 to officers and non-commissioned officers who have been for eighteen months in captivity, and 2,000 to civilian invalids, of whom 1,600 will be Germans and 400 British. The British delegates asked that privates should be included among the men to be interned in a neutral country on the ground of eighteen months' captivity, but there were two difficulties: First, it would have been practically impossible to include all the privates eligible, and, secondly, the Germans did not intend to part with any one out of whom they could get work. Officers and non-commissioned officers could not be set to work, but the men could. It could not be said, however, that the private soldiers had been excepted from benefits. Nearly all the seven thousand invalid combatants would probably be privates, and privates would be exchanged under the agreements already prevailing. Lord Newton explained also the apparent disproportion as between Germans and British in the civilian figures. Taking the proportion of the civilian prisoners of the two countries, this agreement really worked out in our favour because there were something like six or seven times as many German civilians in this country as British civilians in Germany. There was this further provision that whereas it might be difficult to discover 400 British civilians sufficiently ill to come within the agreement, it had been stipulated that if this number could not be found the number should be made up to 400 by taking men whose health had been less tried. Lord Newton added in regard to the exchange that the Germans at first suggested Southwold as the place of exchange. That was quite unsuitable and the British delegates suggested a port on the Thames. The Germans pronounced that impossible. As an alternative, Holyhead was mentioned by our Admiralty, but since then Sir Edward Carson had arranged, subject to German concurrence, that Hull should be the port.

Speaking generally of impressions derived from the conference, Lord Newton gave the opinion that the authorities in Berlin did not know a great deal of what was going on in the camps.

Army Medical Arrangements in Mesopotamia.—Major Hunt asked Mr. Macpherson, on July 26th, what provision had been made for the transport of sick and wounded since the disclosures in the report; whether there were suitable motor ambulances, launches, and hospital ships with shallow draft for use on the Tigris and Euphrates; was there ice-making machinery for the hospitals from Basra to our further point about sixty miles north of Baghdad; and what means of locomotion was provided for the medical officers who required to visit the hospitals and different stations. Mr. Macpherson, in reply, said that the question raised points which could not be suitably dealt with by means of question and answer, but he was collecting the desired information, and would be happy to show it to Major Hunt when it was ready.

Naval and Military Pensions (Mesopotamia).—Colonel Yate asked what pension the widows and children of officers who died during the siege of Kut would be entitled under the new Royal Warrant; and to what pension the widows and children of officers who died of cholera and other diseases during the operations in Mesopotamia previous to April of this year would be entitled. Sir A. Griffith-Boscawen replied that in cases where the illness causing

the officer's death was directly traceable to fatigue, privation, or exposure incident to active operations, whether under the first or the second part of the question, the pensions to the widows and children would be, before April 1st, on the scale known as the "intermediate," and after April 1st on the scale known as the "highest." The rates were fully set forth in the scale of the new warrant. The rates for the family of a captain or subaltern would be £75 for the widow and £20 for each child before April 1st, and £100 for the widow and £24 for each child after that date. Colonel Yate asked whether it was to be understood that the dependants of those who died in Kut and in the epidemics about the same time in Mesopotamia would not come under the benefits of the new warrant. Sir A. Griffith-Boscawen replied certainly not. If the death is due to fatigue, privation, or exposure incident to active operations, they will come under the provisions of the new warrant, but the new warrant dates, as regards the scale, from April 1st. The pension, therefore, will be at the old rate up to April 1st, and at the new and higher rate after April 1st. Colonel Yate: Then as Kut happened before April 1st this year, the persons concerned will not get the benefit of the new warrant? Sir A. Griffith-Boscawen: Yes, they will.

Royal Army Medical Corps.—Mr. Arthur Samuels asked Mr. Macpherson whether attention had been called to the dissatisfaction felt by the temporarily commissioned officers of the Royal Army Medical Corps with the new form of contract for an indefinite term of service which they were now being asked to sign; and whether owing to such dissatisfaction temporarily commissioned officers had declined to continue their services under the new form of contract. Mr. Macpherson replied that renewal for the period of present emergency applied only to those medical men who came under the provision of the Medical Service Act, and the terms of the contracts brought them under only the same conditions of service as other civilians who were liable under this Act.

The Percentage of Tribunal Appeals.—Mr. Hayes Fisher, in a written reply to Mr. Ferens, states that 2,190 appeals in all have been received by the Central Tribunal since the first Military Service Act came into force. Full information was not available as to the proportion that such total bore to the number of appeals heard by the Local Appeal Tribunals. From information lately received, however, it appeared that an appeal had been made to the Central Tribunal in about 1 per cent. of the cases dealt with by the Appeal Tribunals.

The Growth of War Pensions Work.—Mr. Barnes, in reply to a question by Mr. Gilbert as to complaints of delay in fixing pensions for men discharged from the army and navy, has made a remarkable statement as to the growth of the work of the Pensions Board. He said that the weekly payments had now been authorized to close upon 750,000 men, women, and children. The number of renewals each month was reaching into tens of thousands. The new arrangements for treatment also involved much careful work in a great number of cases, and the preparation of cases for the new Appeals Tribunal promised to add still further to the burden. Mr. Barnes said he had a staff of 3,500, consisting almost entirely of women. None had any pre-war experience of the subject and most had little more than a year's service. The majority of cases of real delay were those in which the finding of the medical board on the man's discharge had not been favourable to him, and inquiries had been set on foot to make sure that no element of doubt in his favour had been left unconsidered.

Institutional Treatment for Invalided Soldiers.—Mr. Pike Pease, answering on behalf of the Pensions Minister, questioned by Mr. Jowett, said that under Article 6 of the new Royal Warrant special allowances equivalent to pension for the highest degree of disablement were payable during a period of treatment or training, and when such treatment was given in an institution a deduction from the allowance was authorized to be made towards the cost of an invalided soldier's maintenance. This deduction had been fixed at the uniform rate of a shilling a day whatever the actual cost of the man's maintenance and treatment might amount to. It left the man, if a private, 20s. 6d. a week for himself, and, in addition, allowances were paid to his wife for herself and the children, or to dependants. This appeared a generous provision, and the Minister was not, on the facts presented by Mr. Jowett prepared to increase it.

Enemy Alien Doctors.—Mr. Macpherson stated, in reply to Mr. King, that enemy alien doctors had been employed to some extent in doing duty in prisoners' camps, but not with very satisfactory results.

THE WAR.

PRIMARY EXCISION AND SUTURE OF GUNSHOT WOUNDS.

EVIDENCE that the plan of primary excision and suture of gunshot wounds, elaborated by British surgeons and practised by them during the last two years in a large proportion of cases, is finding favour with German surgeons is afforded by a recent report by Oberstabsarzt Dr. Hufschmid and Dr. Eckert based on an experience of 207 cases.¹ They explain that the method rests on the fact, clinically and experimentally established, that infection is for at least six hours after wounding a purely local process limited to a few millimetres beneath the wound surface. They consider that this period may safely be extended to forty-eight hours, and they have successfully operated even as late as ninety-six hours after the infliction of the wound. In the earlier cases comparatively simple and readily accessible superficial wounds were chosen, but the method was soon extended with equal success to deep and complicated wounds. The suffering of the patient was greatly reduced, the healing process shortened, and a linear scar obtained in most cases. The chief objection made against simple wound excision has been that the resulting large wound surface greatly lengthened the period of healing; the addition of primary suture has more than neutralized this objection. The technique was simple in principle, the essential point being that in excising the wound the knife should throughout be kept strictly to the healthy tissues, and an endeavour made to separate the whole wound surface entire, as in the excision of a growth. As a rule, the incision was made at least 1 cm. distant from the wound surface, but in the case of muscle 2 to 5 mm. sufficed, and in bone the practice was to chisel away 2 to 3 mm. only. The clean wound thus obtained was then closed, the muscle and fasciae separately with catgut, the skin with silk. As a preliminary to excision, the extent and direction of the track by a probe was ascertained as accurately as possible. In cutaneous and subcutaneous perforating wounds and wounds with retention of the projectile, after dividing the skin over the track with scissors the entire wound surface was separated as a whole by incision in the healthy tissue around. In deeper wounds involving the muscles, whether segmental or oblique, with lodgement of the projectile, it was often impossible to remove the wound in one piece. In such cases the skin and subcutaneous tissue were first incised over the track, and the incision then carefully continued through fascia and muscle, keeping parallel to the wound surface in the healthy tissues and avoiding the wound itself as far as possible. In more superficial wounds it was often possible in this way to carve out the wound entire in a shell of healthy tissue. When, however, the wound cavity was unavoidably opened the main bulk of the separated muscle was removed and the farther course of the track and smaller pockets of the wound isolated with scissors and forceps. In vertical wounds with retention of the projectile the aperture of entry was first enlarged in the direction of the muscle fibres, so as to open up the whole track in the form of a funnel; excision was then proceeded with. In deep perforating wounds of the extremities the track was not opened up, but the canal excised by working from the apertures of entry and exit, and the wound closed except for the insertion of a tube. In many cases of this kind primary suture was omitted; in other cases extensive loss of substance rendered complete closure impossible, and the wound was closed as far as possible at either end and left open in the middle. Where bone formed part of the wound surface a thin layer was carefully chiselled away or removed with the sharp spoon.

The method was not considered applicable to wounds in which phlegmon was already present, nor where the excision would involve injury to important organs. A wound of a flat bone, if not too extensive, was not a contraindication (the authors' observations did not include complete fractures of the long bones, nor injuries to joints), but in injuries of the hand and foot bones the radical removal of the wound surface was often difficult and

generally the skin remaining was insufficient for primary closure. Excision without primary suture was also adopted in situations, such as the distal parts of the limbs, where there was danger of infection of the tendon sheaths; and the same applied to wounds adjoining large vessels and nerves, complete excision of the wound surface being often impossible. In all cases where the musculature rendered immobilization difficult a drainage tube was inserted between muscle and subcutaneous tissue.

The following case illustrated the method:

Grenade wound of right buttock twelve hours previously, measuring 5 by 12 cm.; subjacent muscle lacerated; segmental wound of left buttock 15 cm. long; aperture of entry 2 cm., of exit 5 cm.; muscles extensively lacerated down to the bones. Segmental wound of left gluteal fold 20 cm. long; aperture of entry 1 cm., of exit 3 cm.; muscle lacerated for a depth of 3 cm. Segmental wound of left loin 11 cm. long; apertures of entry and exit 2 cm.; muscles of the back lacerated for a depth of 1 cm. Wide excision of all wounds after laying open the tracks; muscle, fascia, and skin sutured separately. Drainage tube inserted in one wound. Sutures removed on the tenth day. All wounds healed uninterruptedly, with smooth linear scars.

The following case, in which more conservative treatment was adopted in the first instance, was also of interest:

Segmental wound of buttock from anus to trochanter, received eight hours previously. On account of the thick layer of muscle covering the track division of the muscle, with excision and suture, was not adopted; the apertures of entry and exit were excised and drainage tubes inserted. Two days later gas gangrene developed. The whole thickness of muscle was then divided and the diseased tissues thoroughly excised. The infection was arrested, with loss of fully half the musculature of the buttock. After this experience the authors never hesitated to divide a muscular layer, however thick.

HONOURS.

A SUPPLEMENT to the *London Gazette*, issued on July 26th, contains a further list of honours for conspicuous gallantry and devotion to duty in the field. The list includes the following medical officers:

D.S.O.

Temporary Captain Harold Saunderson Sugars, M.C., R.A.M.C.
He showing magnificent disregard of personal safety in attending to the wounded under heavy fire for five days. On the fifth day his leg was broken, but this did not prevent him from going through heavy shell fire to save the life of a corporal whose main artery had been cut, and who required immediate attention. His fearlessness in crossing the open under continuous and heavy fire to save life or to alleviate suffering was most marked.

Second Bar to Military Cross.

Temporary Captain Allen Coulter Hancock, M.C., R.A.M.C.
He established his advanced dressing station in the village, although it was under very heavy shell fire. He attended and evacuated a very large number of wounded, working all night, finally going out himself along the front to see if there were any left. M.C. gazetted December 11th, 1916; first bar February 15th, 1917.

Bar to Military Cross.

Temporary Captain Clarence Randolph Young, M.C., M.B., R.A.M.C.
For conspicuous gallantry and devotion to duty in attending to the wounded under heavy fire with the utmost disregard for his own safety. The trench in which he had established his forward dressing station was blown in in many places by intense hostile barrage, which continued for an hour. His example had a powerful effect on all the stretcher-bearers, and it was entirely due to his resource and coolness that all the wounded were safely evacuated. M.C. gazetted November 14th, 1916.

Military Cross.

Captain Arthur Chester Armstrong, C.A.M.C.
He displayed great courage and determination in tending the wounded under very heavy fire. His devotion to duty saved many lives.

Lieutenant Ivor Aubrey, R.A.M.C.(S.R.).

He led a party of bearers through heavy shell fire, and collected and dressed wounded all night. This work he carried on in daylight under observation from the enemy and fire, carrying back an officer on his back from the enemy wire.

Temporary Captain John Dorrington Batt, R.A.M.C.

For conspicuous gallantry and devotion to duty in digging out a number of men who had been buried by a shell. Whilst doing so another shell killed and wounded all who were there, and he was partially buried himself. He continued his work of rescuing other men and dressing their wounds regardless of all danger.

Captain William Mervyn Biden, M.B., R.A.M.C.(S.R.)

His organization for the evacuation of the wounded was admirable. With total disregard of danger he personally supervised the stretcher parties, who worked in daylight in full view of the enemy.

Temporary Captain Maurice Smith Bryce, R.A.M.C.

On three occasions he walked through the enemy barrage to the captured trenches, where he treated the wounded and took them back to the field ambulance. He set a splendid example by his fearlessness and devotion to duty.

¹ Bruns's *Kriegschir.*, Heft 36, 1917, p. 147.

Captain (acting Major) Harold Buck, C.A.M.C.

He led his bearers with great gallantry and was responsible for the evacuation of a large number of wounded men. He set a fine example to all ranks.

Captain Alva Burton Chapman, C.A.M.C.

One of our planes being shot down he went to the assistance. On his way he was wounded in the head. He continued on his way to the machine, which was being heavily shelled, attended to one of the occupants, and had him carried away.

Temporary Captain Claude Norman Coad, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty in proceeding alone, under intense enemy barrage, to the aid of a wounded officer, whom he brought safely back under circumstances of the greatest personal risk over ground swept by enemy fire. He spent the night in No Man's Land, displaying the highest courage and devotion to duty in evacuating the wounded under continual heavy fire.

Captain Waring Gerald Cosbie, C.A.M.C.

He led his bearers into the open under heavy fire, and rescued many wounded men. He worked continuously for forty-eight hours under very heavy fire.

Captain William Creighton, C.A.M.C.

For conspicuous gallantry and devotion to duty when in charge of an advanced dressing station. He took command of a party and searched for wounded for six hours under heavy shell fire, bringing in all our wounded as well as those of the enemy. His gallantry was most inspiring to his men.

Captain Robert Scott Cumming, M.B., R.A.M.C. (S.R.).

For thirty-six hours he worked continuously in evacuating and dressing wounded under heavy shell fire. Throughout he set a magnificent example to those under him.

Temporary Captain Otto de Muth, M.D., R.A.M.C.

For conspicuous gallantry and devotion to duty whilst attending to the wounded under very heavy fire. His initiative and total disregard of danger enabled the evacuation of the wounded to be successfully carried out during a very trying period. No personal danger seemed too great for him to face in the performance of his duties.

Temporary Captain Herman Gerald Dresing, R.A.M.C.

After being shelled out of his dressing station, he took up another position, and continued throughout the day, and performed operations under heavy shell fire, which was causing continual casualties around him.

Temporary Captain Alexander Galletly, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty in taking bearer parties forward under heavy fire to collect wounded from a front line trench. His conduct throughout was admirable. He was continuously on duty for forty-eight hours.

Temporary Captain James Gaston, M.B., R.A.M.C.

He attended the wounded of five other units beside his own throughout the day. The next day he led a party out in front and recovered twelve more wounded who were lying out. Throughout he set a splendid example to all.

Temporary Captain George Charles Gaynor, R.A.M.C.

He showed magnificent disregard of danger in going constantly through heavy barrage to fulfil his medical duties, greatly assisting and encouraging all ranks by his example. He has on previous occasions performed similar gallant work.

Temporary Captain Austin Charles Giles, R.A.M.C.

Though suffering severely from gas poisoning, and unable to stand without assistance, he continued for many hours to attend to wounded and gassed men, refusing to rest himself till all had received attention.

Captain William Hale (junior), C.A.M.C.

He established a dressing station in a forward area, and worked untiringly for sixty hours under fire, dressing the wounded. He set a fine example of courage and determination.

Temporary Captain Robert Hannah, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty in attending to the wounded under very heavy shell fire. He also made four journeys into No Man's Land, under shell, rifle, and machine-gun fire, and brought in the wounded and attended to them. He set a magnificent example of fearlessness to the men.

Temporary Captain Ronald Hodson, M.B., R.A.M.C.

When in charge of the bearers he ensured the rapid clearance of wounded by closely following the advance of shell fire. Throughout he set a fine example of coolness and courage.

Captain Edward Shapter Jeffrey, C.A.M.C.

Under continuous shell fire he directed and steadied the stretcher parties. His fine example and courage enabled all wounded to be cleared before daylight.

Captain Richard Wellington Kenny, C.A.M.C.

He unceasingly attended wounded in his dressing station. He improvised an additional station in an adjacent trench and carried on his work under shell fire. He has done previous good work in the same capacity.

Captain Charles Kerr, C.A.M.C.

He continually exposed himself to heavy fire, with the result that every wounded man was cleared as soon as his wounds were dressed. He has on several occasions shown most unselfish devotion in the care of wounded.

Captain Maurice Bertram Lawrie, S.A.M.C.

At great personal risk he established and carried on an advanced bearer post. He gave a fine example of courage to those under him in the face of heavy shell fire in clearing the forward area of wounded.

Temporary Captain William Leslie, M.B., R.A.M.C.

For six days he was at the A.D.S., which was shelled almost continuously. His work had to be done out in the open, where there was very little cover, owing to the accumulation of cases. His work throughout deserves the highest praise.

Temporary Captain Joseph Paterson Lusk, M.B., R.A.M.C.

He attended the wounded where they fell by the enemy trench under very heavy fire. His disregard of self and consideration for the wounded set a splendid example to all.

Temporary Lieutenant James Wallace Macfarlane, M.B., R.A.M.C.

He went through a heavy gas shell fire to dress a wounded man. Finding it impossible to perform this work with the gas mask on, he removed it at great risk and completed his task before putting it on again.

Temporary Captain Robert John Bowman Madden, R.A.M.C.

He worked continually for thirty hours under heavy fire leading and organizing stretcher-bearers. Throughout he set a splendid example.

Captain Robert Paul Scott Mason, R.A.M.C.

For conspicuous gallantry and devotion to duty in tending the wounded of several batteries. To do this he had to pass through very heavy shell fire, and on this, as on previous occasions, he showed absolute disregard of personal danger.

Captain Samuel McCausland, R.A.M.C.

Under very heavy and continuous shell fire he systematically searched from cellar to cellar of a village until he had successfully cleared his part of the village of all wounded. These included many who had been lying there for days, and who could not be moved owing to the intensity of the enemy barrage. He worked unceasingly amidst conditions of the greatest possible danger for thirty hours.

Captain Hugh Roy Mustard, C.A.M.C.

For conspicuous gallantry and devotion to duty in dressing the wounded of a battery in the open, exposed to heavy shell fire, for two hours. He then continued at an exposed post for three days dressing wounded, and he has on several occasions exhibited great courage and devotion of the same kind.

Temporary Captain Archibald Gladstone Naismith, M.B., R.A.M.C.

When supervising the erection of an A.D.S. he was knocked down and stunned by a shell which wounded most of the party. On recovery he at once attended to the wounded, and remained until this was completed.

Temporary Captain Kenneth Montague Nelson, R.A.M.C.

For conspicuous gallantry and devotion to duty in attending to the wounded with the utmost fearlessness under heavy shell and machine-gun fire. He constantly went out to our most advanced positions in aid of the wounded, and his careful search of the battlefield resulted in most of the more serious cases being found and brought back to the dressing station. His unselfish devotion was directly the cause of many lives being saved.

Temporary Captain William Bentley Purchase, R.A.M.C.

For conspicuous gallantry and devotion to duty in attending to a wounded driver, with whom he remained under heavy shell fire until he died, having ordered two of his men to go to a place of safety. He had previously showed exceptional bravery and promptness in responding to a call for medical help earlier in the day, when four officers had been killed by shell fire in the battery.

Temporary Captain Arthur Carlile Sturdy, F.R.C.S., R.A.M.C.

He attended wounded for many hours under heavy fire. He showed a complete disregard for danger in organizing search parties, and recovered wounded who had been left for several days.

Captain Donald George Kennedy Turnbull, C.A.M.C.

He showed continual fearlessness and splendid devotion in making his way under the heaviest fire to the most advanced parts of the battlefield to establish dressing stations and attend to the wounded. No undertaking seemed too perilous for him; he constantly dressed wounded in the front line, and the example he set to his stretcher-bearers and carrying parties was at all times beyond all praise.

Captain Joseph Stephen Wallace, R.A.M.C.

For conspicuous gallantry and devotion to duty when in charge of bearing parties, in so organizing and handling his stretch-bearers amidst heavy shell and gas barrage that a very large number of our wounded were brought into safety. His conduct was conspicuous throughout for coolness, good judgement, and total disregard of danger. He had been knocked out by gas the day before, but insisted on remaining at his post.

Captain John Rollo Noel Warburton, R.A.M.C.

He showed great courage and devotion in his treatment of wounded. The press of cases was very heavy, and he worked all night and the next day.

Temporary Captain John Victor Williams, M.B., R.A.M.C.

He took a party of bearers up, and, crossing the open under very heavy shell fire, dressed all the wounded and returned with them, going out later and coming in with the lost squads. He worked for four nights and days.

A bar to the D.C.M. has been awarded to one non-commissioned and one private of the R.A.M.C., and the D.C.M. to several non-commissioned officers and privates of the R.A.M.C.

A supplement to the *London Gazette* issued on July 23th, containing a further list of non-commissioned officers and men who have been awarded a bar to the Military Cross, includes a number of members of the R.A.M.C.

OFFICERS COMMENDED.

A supplement to the *London Gazette* published on July 27th contains a list of officers whose names have been brought to the notice of the Secretary of State for War for distinguished services rendered in connexion with the war. The following medical officers are included in the list:

Surgeon-Generals: J. C. Culling, A.M.S., R. H. Quill, M.B., ret. pay, late A.M.S.

Colonels (temporary Surgeon-Generals): R. S. F. Henderson, M.B., K.H.P., A.M.S., M. T. Yarr, C.B., F.R.C.S.I., A.M.S.

Colonels: Sir R. N. Campbell, K.C.M.G., C.B., C.I.E., ret. I.M.S., C. A. Hodgets, C.M.G., C.A.M.C., D. W. McPherson, C.A.M.C., Sir J. Magill, K.C.B., M.D., ret. pay, R. J. Millard, C.M.G., A.A.M.C., A. Peterkin, M.B., ret. pay, late A.M.S., G. S. Rennie, C.A.M.C., R. J. S. Simpson, C.M.G., M.B., ret.

pay, A.M.S., C. R. Tyrrell, C.B., ret. pay, A.M.S., D. Wardrop, C.B., C.V.O., M.B., ret. pay, A.M.S.

Honorary Colonel C. J. Bond, Consulting Surgeon, Northern Command.

Temporary Colonel James Galloway, C.B., M.D., F.R.C.P., F.R.C.S., A.M.S.

Surgeon-Lieutenant-Colonels and Honorary Surgeon-Colonels D. Hepburn, M.D., R.A.M.C., R. J. Reece, C.B., M.D., H.A.C.

Surgeon-Lieutenant-Colonel Sir W. R. Crooke-Lawless, C.B., C.I.E., M.D. (Res. of Off.).

Lieutenant-Colonel and Brevet Colonel Sir B.G. Seton, Bt., C.B., I.M.S.

Lieutenant-Colonels J. Chaytor-White, C.M.G., M.D., ret. I.M.S., J. M. Cotterill, M.B., F.R.C.S., R.A.M.C., Sir P. J. Freyer, K.C.B., M.D., I.M.S. ret., D. Harvey, M.D., R.A.M.C., W. T. Hayward, C.M.G., A.A.M.C., T. E. V. Hurley, C.M.G., A.A.M.C., H. Littlewood, F.R.C.S., R.A.M.C., J. N. MacLeod, C.M.G., C.I.E., M.B., F.R.C.S., ret. I.M.S., B. E. Myers, M.D., N.Z.M.C., F. F. Perry, C.M.G., C.I.E., F.R.C.S., ret. I.M.S., G. S. A. Ranking, M.D., R.A.M.C., late I.M.S., J. C. Robertson, C.I.E., M.B., I.M.S., S. B. Smith, C.M.G., I.M.S., T. H. Sweeney, C.M.G., F.R.C.S.I., ret. I.M.S., W. Turner, ret. R.A.M.C.

Temporary Lieut.-Colonels: W. N. Barron, M.V.O., R.A.M.C.; W. L. W. Marshall, R.A.M.C.

Temporary hon. Lieut.-Colonel M. H. Gordon, C.M.G., M.D., R.A.M.C.

Majors (temporary Lieut.-Colonels): H. T. D. Acland, F.R.C.S., N.Z.M.C.; D. S. Wylie, M.B., F.R.C.S., N.Z.M.C.

Major and Brevet Lieut.-Colonel (temporary Brigadier-General) A. C. Geddes, C.B., M.D. (Unattached List, T.F.)

Majors: G. A. D. Harvey, C.M.G., R.A.M.C.; P. S. O'Reilly, C.M.G., R.A.M.C.

Temporary Major A. D. Reid, C.M.G., R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Died of Wounds.

CAPTAIN W. A. SNEATH, M.C., R.A.M.C.

Captain Wilfrid Archer Sneath, M.C., R.A.M.C., was reported as having died of wounds in the casualty list published on July 26th. He was educated at the Victoria University, Manchester, where he acted as demonstrator of anatomy, and graduated M.B. and Ch.B. in 1910, also taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1912, and the F.R.C.S.Eng. in 1913. After filling the post of house-surgeon at Manchester Royal Infirmary and at the Seamen's Hospital, Greenwich, he went into practice at Ashton-under-Lyne. He took a temporary commission as lieutenant in the R.A.M.C. on September 11th, 1914, was promoted to captain on completion of one year's service, and received the Military Cross on September 22nd, 1916.

Died on Service.

TEMPORARY SURGEON E. S. CALTHROP.

Temporary Surgeon Edward Spencer Calthrop, R.N., died in London on July 30th, of toxic neuritis. He was the second son of the late Mr. Edward Calthrop, and was educated at Charing Cross Hospital, taking the M.R.C.S. and L.R.C.P.Lond. in 1909, and the M.B. and B.S.Lond. in 1910. He took a temporary commission as surgeon in the Royal Naval Division in 1914.

LIEUT.-COLONEL F. J. C. HEFFERNAN, R.A.M.C.

Lieut.-Colonel Francis Joseph Christopher Heffernan, R.A.M.C., was reported as having died on service, in the casualty list published on July 26th. He was born on June 4th, 1874, educated in the medical school of the Royal College of Surgeons in Ireland, and took the diplomas of L.R.C.S.I. and L.R.C.P.I. in 1897, and the F.R.C.S.I. in 1902. Entering the R.A.M.C. as lieutenant on July 27th, 1898, he became captain on July 27th, 1901, major on April 27th, 1910, and lieut.-colonel on March 1st, 1915. He served in Africa in 1901, in the expedition on the Gambia river, and received the medal and clasp.

LIEUTENANT S. C. ELLISON, R.A.M.C.

Lieutenant Samuel Charles Ellison, R.A.M.C., was reported as having died on service, in the casualty list published on July 26th. He was educated at the universities of Belfast, where he gained a medical scholarship, and of Edinburgh, where he graduated M.B. and Ch.B. in 1902, and M.D. in 1904, after which he went into practice at Small Heath, Birmingham. He died, we understand, within a week of landing in Egypt. His death has caused

very great regret in Small Heath, where his qualities were highly appreciated. He had only recently taken a temporary commission in the R.A.M.C.

LIEUTENANT J. S. MUNRO, M.B., Ch.B., R.A.M.C.

A Correction.

The casualty list published on July 26th contained the name of Lieutenant J. S. Munro, M.B., R.A.M.C., and in preparing the list printed in our issue of last week it was unfortunately assumed that the notice referred to Dr. James Sutherland Munro of Pendleton, whereas it referred to his brother Dr. John Sutherland Munro, who graduated M.B., Ch.B.Edin. in December, 1916, and took a commission as temporary lieutenant in the R.A.M.C. on January 20th, 1917.

R. C. TWEEDY, M.D.

Dr. Reginald Carlyon Tweedy died at Newquay, Cornwall, on July 12th. He was educated at St. Bartholomew's Hospital, took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1892, and the degree of M.D.Durham in 1913. After acting as house-surgeon of Birmingham General Hospital, and senior resident medical officer of the Seamen's Hospital, Royal Albert Docks, he went into practice at Kenilworth, where he was honorary medical officer of Kenilworth Convalescent Homes, and certifying factory surgeon. During the present war he had served as surgeon to Lady Sykes's French Red Cross Hospital at Dunkirk, and held a commission as temporary major in the R.A.M.C.

Wounded.

Staff Surgeon E. L. Atkinson, R.N.

Lieut.-Colonel A. W. F. Sayres, R.A.M.C.(T.F.).

Captain P. W. Edwards, R.A.M.C.(S.R.).

Captain F. Ellis, R.A.M.C.(T.F.).

Captain E. L. Graves, Australian A.M.C.

Captain H. H. Hepburn, R.A.M.C. (temporary).

Captain R. A. Ireland, Canadian A.M.C.

Captain J. W. Linnell, R.A.M.C. (temporary).

Captain E. Mansfield, R.A.M.C. (temporary).

Captain C. G. Skinner, R.A.M.C. (temporary).

Wounded and Missing.

Captain E. D. F. Hayes, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Browne, Arthur Davies Lang, Lieutenant Connaught Rangers, younger and only surviving son of Colonel A. Lang Browne, A.M.S., Ilminster, Somerset, killed recently. He received his commission in December, 1915, and had served in Mesopotamia and in France. His elder brother, Captain John Agnew Lang Browne, Queen's Royal West Surrey Regiment, was killed at Festubert on May 17th, 1915.

Dick, James Douglas, Captain R.N., commanding H.M.S. Vanguard, son of Sir James Nicholas Dick, K.C.B., Medical Director-General of the Royal Navy from 1888 to 1898, killed when the Vanguard was blown up on July 9th, aged 45. He joined the navy as a midshipman on January 1st, 1887; became captain on December 31st, 1908; and had commanded H.M.S. Black Prince for a year before he was appointed in January, 1916, to the Vanguard, which he commanded in the battle of Jutland on May 31st, 1916.

Fleming, Ernest Cole, Major Royal Field Artillery, youngest son of the late Dr. W. J. Fleming, killed July 18th. He was born in May, 1834; entered the R.F.A. from Woolwich in July, 1903; became captain on January 30th, 1914; and had recently been promoted to major. He received the Military Cross last January.

Jefferson, Ingleby Stuart, Lieutenant R.N., elder son of Dr. W. D. Jefferson, Medical Officer of Health, Ripon, killed July 21st, aged 24. He was educated at Aysgarth School, Yorkshire, and had received the Royal Humane Society's medal for rescuing a soldier from drowning.

Laxton, Archer Benjamin, Second Lieutenant Royal Field Artillery, second son of the late Mr. T. L. Laxton, formerly surgeon-major Staats Artillerie, Pretoria, killed July 21st, aged 19. He received his commission in August, 1916.

Pasteur, William Raymond, M.C., Captain Royal Field Artillery, only son of Colonel William Pasteur, A.M.S., killed July 10th. He got his first commission on November 17th, 1914.

Welsh, C. C., Captain Royal Field Artillery, elder son of Dr. Welsh of Biggleswade, killed July 17th, aged 27. He got his first commission on February 27th, 1915.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

England and Wales.

HEALTH AND EYESIGHT OF LONDON SCHOOL CHILDREN.

IN 1915 the London County Council decided, as a matter of war economy, that instead of all children being subjected to a thorough medical examination on entering elementary schools, only those specially selected by the teachers, and those who from their general appearance were considered by the inspecting doctor to need detailed examination, should be so examined. At the meeting of the Council on July 31st the Education Committee reported that the annual report of the school medical officer for the year 1916 had made it plain that the new methods of inspection had proved unsatisfactory, and that a certain number of children suffering from hidden defect had escaped notice. The school doctors also experience a certain amount of strain in examining thirty children during a session. The Council decided to revert to the former methods of medical inspection, and authorized the appointment of additional school doctors to meet the need. In 1915 the Council decided that no further action should be taken with regard to the provision of additional schools for children suffering from high myopia. It was now reported that 325 children were awaiting admission to such schools, and it was decided that the provision of further accommodation for myopic children was a matter of urgent importance, that the former resolution be rescinded, and that special accommodation for myopic children be provided in thirteen classes in eleven different centres.

HEALTH OF LONDON IN 1916.

The medical officer of health for the county of London, Dr. W. H. Hamer, has issued his report for the year 1916, together with his report as school medical officer for the same period. The health of London during 1916, when more water in a literal sense flowed under London Bridge than in any year since 1883, compares favourably with that during 1915, in which the weather was almost as wet. The unusual rainfall of the past seven years, Dr. Hamer states, has unquestionably exercised a considerable influence upon the public health. The two reports are as usual bound together in the familiar orange cover, but the number of pages is greatly reduced. We hope to consider the more noteworthy conclusions in an early issue of the JOURNAL.

Scotland.

PARLIAMENTARY REPRESENTATION OF EDINBURGH AND ST. ANDREWS.

SIR WILLIAM WATSON CHEYNE, F.R.S., has accepted the invitation of a representative committee of the constituency to become a candidate for the vacancy in the parliamentary representation of the universities of Edinburgh and St. Andrews, caused by the elevation of Sir Christopher N. Johnston, K.C., to the judicial bench. In his address, published in full in our advertisement columns, Sir Watson Cheyne states that he has always belonged to the Conservative and Unionist party in politics, and will continue to associate himself with that line of political thought; but he adds that at the present time, when we are struggling for our very existence, party politics must be put completely in abeyance, and all must devote their energies to the task of defending the country from an utterly unwarranted attack, and of retaining our most cherished freedom. He will therefore give his whole-hearted support to the present Government in the noble struggle in which we are engaged. Sir Watson Cheyne graduated M.B., C.M. at Edinburgh in 1875. He had been Lister's house-surgeon at the Edinburgh Royal Infirmary, and when Lister became professor of clinical surgery at King's College, London, in 1877, Sir Watson Cheyne became his first house-surgeon there. Sir Watson Cheyne has remained connected with that institution ever since, and is now Professor of Clinical Surgery in King's College. Since the outbreak of war he has been Consulting Surgeon in the Royal Naval Medical Service, with the rank of Surgeon-General. He relinquished only the other day the position of president of the Royal College of Surgeons of England.

Correspondence.

ON T.N.T. POISONING, WITH A REQUEST FOR INFORMATION FROM MEDICAL OFFICERS AT THE FRONT.

SIR,—Whilst thanking you for your reference in last week's issue (July 28th, p. 119) to the work of myself and colleagues on trinitrotoluene poisoning in munition works, will you kindly allow me to correct one unguarded statement which might lead into error?

Our experiments show that T.N.T. is just as readily absorbed, and just as poisonous, when taken by the mouth as when taken in through the skin or by any other channel.

The real point is that careful analyses show that the amounts available for absorption by mouth and nose are so minute under actual conditions of labour in the workshops that no danger is to be apprehended from them. On account of the extremely bitter taste of the powder and its irritant action on nasal mucous membrane the wrong impression was produced that poisoning arose from swallowing or inhaling dust and fume. By drawing off measured volumes of factory air, trapping all dust and fume out of it, and weighing these, we were able to show that the amount swallowed by a worker during a shift was infinitesimal (about 6 mg.), that we could ourselves swallow double or treble this quantity for days without any ill effects, and only one of us got a certain amount of cyanosis with a daily dose for a fortnight, at least eightfold the calculated absorption in the factories. Next we showed that when we thoroughly protected our hands we could carry out the same operations in the workshop as the workpeople for the same periods and absorb only traces of T.N.T., although we wore no respirators to prevent swallowing. Then, avoiding the workshops and all sources of dust or fume, we rubbed T.N.T. into the palms of our own hands, and later of those of some hundreds of volunteers, amongst oncoming T.N.T. workers, and proved that there is a certain percentage of individuals who possess skins which allow easy passage to the substance, while a large proportion possess considerable resistance.

As a result, we were enabled to prevent the semi-suffocation of many thousands of T.N.T. workers, and save hundreds of pounds weekly in the cost of respirators. Also, to show that cotton gloves were quite useless, and only made the hand soft and more permeable.

Attention could also now be turned from forced ventilation of these open sheds in the country, which had so been shown to be needless, towards methods of keeping shells and workshops clean, and the rapid introduction of mechanical contrivances.

At the same time observations were made by us in the workshops for the first indications of T.N.T. absorption in dangerous amount, and in September last we were able to describe a T.N.T. "facies" antecedent to jaundice, by which a worker could be detected in the early stages of poisoning and removed to other work. This we recommended should be accomplished by the factory doctor patrolling the workshop and picking the cases out. The appearances we then described we now know to be due to cyanosis and dearth of oxygen supply, as are most of the symptoms complained of by patients, such as giddiness, breathlessness, drowsiness, nausea.

The typical appearances in a person who ought to be removed were given as "a pale face lacking in expression and like anaemia but peculiar in itself, lips that can scarcely be described as cyanosed but of an ashen-blue colour, similar gums, and perhaps a faint trace of yellow on the conjunctivae, the rest of the skin showing no icterus."

As a result (1) of this early detection in the actual workshops at the pre-jaundice stage, and (2) of the discovery that the most important channel of entry is the skin having led to improved cleanliness of workmanship, both minor T.N.T. illness and toxic jaundice have now shrunk to a fraction of their former magnitude, and T.N.T. operations are now almost as safe as any other. The savings in labour and money, and the improvement in health and workmanship, have been enormous.

At a certain period when causation of T.N.T. illness was not understood, shells were turned out covered by a

film of T.N.T.; this is now largely obviated. It is known that a certain amount of dermatitis has been observed abroad amongst men handling shells. The cyanosis of minor T.N.T. illness, or even in a few cases toxic jaundice, may have passed without notice. I should be glad to hear from any one who has observed cases of jaundice of uncertain origin or cases showing the symptoms of minor T.N.T. illness detailed above.—I am, etc.,

8, Pembroke Villas, Richmond,
Surrey, July 30th.

BENJAMIN MOORE.

BRILLIANT GREEN AS AN ANTISEPTIC.

SIR,—In reference to the valuable and suggestive article on acriflavine, etc., by Messrs. Browning, Gulbransen, and Thornton of the Bland-Sutton Institute of Pathology, I should like to mention one aspect of the matter not dealt with—for obvious reasons. It is that of *economy*.

After experimental proof in every sort of case had convinced me of the value of brilliant green, I was interested to find that my surgical nursing staff was equally enthusiastic in spite of occasional stained hands and clothes. The extraordinary results, and the increased comfort of the patients, and the diminished number of dressings to be done had convinced them also. The wounded from Mesopotamia arriving at Cumballa Hospital, Bombay, differed in some degree from most of those arriving in England from, say, France. For geographical reasons it was usually three weeks before they got to Bombay, and wound infections were strongly entrenched. *B. pyocyaneus* in particular, especially in septic compound fractures, was hard to overcome.

After preliminary surgical treatment—in some cases already carried out in Mesopotamia—ordinary absorbent gauze, wet with 1 in 1,000 brilliant green (aqueous), was applied to the wound, inserted into sinuses, and covered with protective; even the foulest case was dressed not more than once daily, and surface infections often only alternate days. Cultures taken from the “pus” were used to control the clinical improvement, and even in the Bombay climate, so favourable to the growth of organisms, wound infections were overcome by the resistance of the patient aided by the brilliant green.

As regards the actual economy in dressings (apart from factors like the time occupied and the relief to patients' feelings due to less frequent dressings) it was found that during two periods of six weeks, with and without the use of brilliant green respectively, the quantity of material consumed was roughly as 1 is to 2. The average number of patients under this treatment at one time was 85.

I am grateful to my late commanding officer, Lieut.-Colonel J. W. Prescott, D.S.O., R.A.M.C., for much encouragement and advice.—I am, etc.,

ARTHUR F. COLE, Captain R.A.M.C.

Cambridge Hospital, Aldershot, July 28th.

DR. ADAMI'S CROONIAN LECTURES.

SIR,—Dr. Adami is suffering from an illusion. I have never had, and at present have not, the intention of discussing a scientific theory with him. His manners and methods render that impossible. My purpose in writing to you was to expose (as I explained in my letter of July 14th) the offences against the laws of social intercourse of which he has been guilty in making public use of a confidential communication from me without my permission and in using vulgar ridicule and rhetorical abuse when entrusted by a learned and dignified College with the privilege of addressing it. I also took occasion to show that Dr. Adami erroneously claimed novelty for the view that the activities of the bacteria are susceptible of change under changed environment—a view which forty years ago I was one of the first to advance, although Dr. Adami goes out of his way to declare “without rhyme or reason” that I am opposed to it. I showed that his confusion of thought on this and related matters of fact is due to his misapprehension of the significance of the words “variation,” “variability,” and “adaptation.”

Dr. Adami admits the offences and the blunders to which I have drawn attention; indeed he cannot deny the plain evidence of his own words. There is not (as Dr. Adami erroneously asserts) a “main issue” or “main argument” beyond these facts, in which I am concerned.

When a man stands convicted on his own confession, as

Dr. Adami does, he either has the grace to express his regret and offer an apology for his offences and blunders, or he has not. Dr. Adami has not shown that grace; until he has, I decline to pursue the matter any further. He writes airily about “registering hits,” and “outers,” and “a German naval victory” as though the College of Physicians and the columns of a great medical journal were a sort of children's playground in which he is at liberty to “run amok” with a pretence of importance accompanied by violence to bystanders, and then run away without apology or penalty.

Even after his exposure Dr. Adami continues to write with regrettable flippancy. He commences his letter to you of July 21st by stating that by “academic” he means a man who “is more concerned with upholding the teaching and tradition of the schools than with the advance of his subject.” And then he is so far reckless of his own reputation for discrimination and knowledge of character as to apply this description to me. He forgets that others can judge of the aptness of his definition and illustration, and also that in his first lecture he ventured to invoke “the shade of Harvey,” one of the greatest of “academic biologists.”—I am, etc.,

London, W., July 26th.

E. RAY LANKESTER.

THE CO-ORDINATION OF BRITISH MEDICAL POLICY.

SIR,—I am both a member of the British Medical Association and of the Panel Medico-Political Union, and I think there is need and room for both. The British Medical Association is much the older of the societies, and in the past it has done a great deal for the progress of the medical profession, but after everything has been said, it will be found that what has been done has been done when there was no serious opposition. The British Medical Association has no real strength behind it, and I understand that by its present constitution it never can possess strength. What is to be done? Dr. Coode Adams tells us a responsible member of the Government made it plain to his deputation that there is no hope for us without a very firm union of the whole profession, with strong and strict discipline behind it.

I venture to suggest that the British Medical Association should retire from its present undignified position, and be contented to accept the position of the great scientific association for the education and increased information of the profession, and leave to the Medical Union the business of looking after the material interests of the profession.

The British Medical Association has a considerable organization; this it could hire to the Union for such a sum as would maintain the Scientific Society in comfort. Both societies belong to the profession, and will be very long to the whole of the profession, but they will exist for different purposes, and I believe the officials of the British Medical Association will serve both. The BRITISH MEDICAL JOURNAL will then be the only journal of the profession, as it will probably become necessary to buy up the others, and the Union will have its place in the JOURNAL under some such conditions as the SUPPLEMENT has to-day. The managers will be different, as the Union will probably be governed by younger and more energetic men than the British Medical Association, and it will contain amongst the managers one or more purely business men.

I believe the Union will progress, and as its members increase it will be able to bring pressure which will bring in all consulting physicians and surgeons, etc., and all the newly-qualified medical men.

I am a practitioner of nearly forty years' standing, but I hope to live to see the day when the whole profession will be united in a firm union. I am not proud of the profession. Because of the complete want of cohesion and the absence of intimacy of the members, members are guilty of many shameful actions towards each other, actions which I believe would be impossible if there were a union which would necessarily hold meetings frequently in the larger villages as well as in the towns.

As the union increases in strength I would invite dentists and veterinary surgeons to join with us, for we are all concerned in the treatment of disease. I would even go further than that. After our union has been proved to be the great success that is, certain, the doctors

of other lands will follow our example. I would invite them all to affiliate with us. Then we would see the medical profession become the greatest, the most humane, the most beneficent, the most useful association of men the world has ever known.—I am, etc.,

Birtley, July 24th.

J. H. OGILVIE.

QUO VADIS?

SIR,—It is obviously high time that the officials of the British Medical Association published the evidence in their possession as to the truth or falsity of Dr. Fordyce's statement that in 1912 the Government had ready a whole-time service scheme—or any other *real* scheme—and was prepared to work it. One knows there are people who still believe that Lord Kitchener survives and that the "mysterious prisoner" still resides in the Tower of London, or that the Russians really did pass through England in 1914, but one smiles when Dr. Davies bases his very definite assurances on proofs "which cannot be stated" or on witnesses who "cannot be named." We all know those proofs and those witnesses.

I note that Dr. Davies does not attempt to meet the main point, namely, that the so-called *débâcle* of 1912 was due to the fact that the remuneration finally offered was good and sufficient, and the terms honourable and satisfactory. Surely the time has come when the story of the whole-time service men and the hordes of recently qualified Scotsmen and Irishmen enlisted by Mr. Lloyd George and his subordinates in 1912, should finally be exploded, lest, like the peripatetic Russians, it crops up again next year. I call upon the officials of the Association forthwith to publish the facts.—I am, etc.,

Hove, July 29th.

C. RAWDON WOOD.

*** Dr. Wood's comparison of the story of the whole-time service which was to break down the resistance of the profession at the beginning of the operation of the Insurance Act with the story of the Russian army which passed through England seems to us very apt. The comparison is, perhaps, the closer because the Government had perhaps a small number of men—say, one hundred—ready to go anywhere, while there were at the time of the rumours probably certain Russian officers in this country for consultation purposes, whose numbers were magnified by popular imagination.

MEDICAL STUDENTS IN AND OUT OF THE RANKS.

SIR,—I should be glad if you would allow me to supplement and endorse the remarks of "J. A. A." in your issue of July 21st. My son, having finished his second year when war broke out, and fired with a generous patriotism enlisted as a private. On my advice he joined the R.A.M.C. He was so keen at his medical work that he had spent most of his vacations in 1914 doing dressings in the out-patients' and in the accident room. He was up to time with his various examinations. I therefore thought that he would find an opportunity of proving himself of real use in the army, as doubtless surgeon-probationerships would be established to utilize the services of medical students. He passed through all the grades up to sergeant-major, and was then actually sent back from France to this country for a commission in the fighting ranks. At the time—November, 1915, nearly fifteen months after he had joined up—I wrote to the Central Medical War Committee in London, and told them the facts, and asked if something else more in accordance with his desires could not be found for him. To that letter I have as yet had no answer, not even an acknowledgement that it was received. To-day he is in the front line, and as it is nearly three years since he opened a medical book I ask what can he do if he returns safe and sound when the war is over? Is he to begin his reading all over again along with a parcel of freshers? He knows well that the fellow students of his year are, as "J. A. A." says, benefiting in their work and in their appointments through having resisted the call of patriotism.

Moreover, owing to the demands of the War Office, many of these men are actually fully qualified—owing their degrees to an indulgent system of examination. Thus these shining patriots are benefiting by the self-denial of their brother students who thought first and only and all the time of the call of their country. In this way I can

assure your correspondents that patriotism *does* pay; it pays now and even more so in the future those who have turned a deaf ear to its call. I make bold to say that the British Medical Association has conspicuously failed its members in this important matter.—I am, etc.,

Manchester, July 29th.

BASIL W. CONWAY.

THE SELECT COMMITTEE ON ARMY MEDICAL RE-EXAMINATIONS.

SIR,—Our sincere thanks are due to Colonel C. R. Tyrrell, R.A.M.C., for his loyal and manly remarks before the Army Medical Re-examination Committee.

The overworked civilian medical men have from the earliest days of the war come forward freely to help the medical boards and the tribunals, and now their work is being abused by ill-informed persons. The civilian doctors have very rarely had anything to do with the classification of the men they have examined, and the presidents of the boards have been fettered, and neither are therefore responsible.

These re-examinations would never have been required if the Government had not been afraid of calling up all fit men up to 30 years of age irrespective of their work. How many Frenchmen of that age are there in civil life?—I am, etc.,

July 31st.

A VICTIM.

THE LATE DR. HACKMAN OF PORTSMOUTH.

SIR,—I take the opportunity of sending a return of the subscriptions I have received for the Hackman Memorial, (A) in reply to the letter published in the JOURNAL a month ago, and (B) in response to the appeal to the Annual Representative Meeting on July 26th:

(A)		£ s. d.	£ s. d.

In addition to these—of which I have vouchers—the sum of £14 19s. 6d. was given at the door, and of the donors of this considerable amount I have not the names; I can, therefore, only ask them to take my statement (on trust) that it is an accurate account of the receipts.

I wish to thank the Chairman of the Representative Body and Drs. Sheahan, Treasure, and Brierley, for their valuable help, and this applies to the officials of the Association who have given me excellent advice. This brings me to my last point, namely, to ask each and all of the representatives to bring the case before their friends in the Divisions. We can find use for a lot more money yet, and I hope I may not be appealing in vain.

The following donations are promised, namely:

	£ s. d.

—I am, etc.,

JAMES GREEN,
Honorary Secretary, Southern Branch.

Brandon House,
Mile End, Landport, Portsmouth, July 29th.

The Services.

EXCHANGE.

MEDICAL OFFICER to Base Hospital in France desires exchange with officer on home station (hospital or otherwise).—Address No. 2550, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Universities and Colleges.

UNIVERSITY OF DUBLIN.

SCHOOL OF PHYSIC, TRINITY COLLEGE.

THE following candidates have been approved at the examinations indicated:

FINAL MEDICAL, PART I.—*Medical Jurisprudence and Hygiene, Materia Medica and Therapeutics, Pathology*: *V. M. Synge, *W. F. McConnell, *L. J. P. Murphy, *W. P. Elford, *A. J. Vorstex, Ethel M. Luce, F. W. Godbey, D. McElwee, B. Fitz-James Haythornthwaite, Gertrude Rice, R. B. M. Smartt, F. J. G. Battersby (Pathology completing examination), J. W. Scharif (Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene).

PART II.—*Medicine (M.B.)*: B. A. McSwiney, G. W. B. Shaw, H. Banks, A. H. Davidson and P. Rock (equal); W. J. Hamilton, H. J. Rice, H. Brill, W. L. Young. *Surgery (B.Ch.)*: *E. D'A. McCrae, *A. R. Barlas, W. P. Lubbe and H. H. Molloy (equal); J. R. Brennan, M. C. Dippenaar, S. A. Clark, C. P. Chambers, A. H. Davidson, F. W. P. Sullivan; J. J. Keatley and J. B. McGrahan (equal); Meta G. Jackson, A. G. Wright; W. J. Hamilton and P. C. Parr (equal). *Midwifery (B.A.O.)*: P. Rock, G. W. B. Shaw, C. G. Ambrose, R. W. Nesbitt, F. Gill, P. A. Dormer, T. M. Bentley, H. Brill, J. E. Hill, C. P. Chambers, G. Marshall.

* High marks.

M.Ch.—H. de L. Crawford.

M.A.O.—Mabel A. D. Crawford.

The following prizes have been awarded:

John Mallet Purser Medal (Physiology), Janie M. Cummins. Daniel John Cunningham Memorial Medal and Prize (Anatomy), E. H. C. Allen. Medical Scholarship (Anatomy and Physiology), J. H. Coolican. Stewart Scholarship (Anatomy and Physiology), N. Long. FitzPatrick Scholarship, E. D'A. McCrae.

LONDON SCHOOL OF TROPICAL MEDICINE.

THE following candidates have been approved at the examination held at the termination of the fifty-fourth session:

*M. Erfan, P. M. Antia, P. A. Dingle, Miss S. Dolmer, R. R. Syquia.

* With distinction.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMMITTEE was held on July 25th, when Sir Frederick Taylor, Bt., presided. Dr. E. P. Poulton was admitted a Fellow of the College, and licences to practise physic were granted to ninety-seven candidates who had passed the necessary examinations.

Diplomas in Public Health.

Diplomas in Public Health were granted in conjunction with the Royal College of Surgeons of England to the following candidates:

Luis Gregorio Chacin-Itriago, M.D. (Venezuela), L.R.C.P., M.R.C.S., St. Bartholomew's and King's College; Herbert Davies, M.B., B.S.Lond., Middlesex and University College; Mostafa Dia, L.R.C.P., M.R.C.S., Cairo and St. Mary's; Muriel Ann Lloyd, M.B., B.S.Lond., Royal Free Hospital and University College; and Robert Septimus Walker, L.R.C.P. and S. Edin., L.F.P. and S. Glasg., Edinburgh and University College.

Election of College Officers.

The election of censors, other college officers, members of Committees, and examiners then took place. The censors elected were: Drs. Samuel Hatch West, Hector W. G. Mackenzie, Sidney Philip Phillips, and Frederick Walter Mott.

After-War Entente Conference.

A communication was received from the Local Government Board, enclosing communications from the Foreign Office, and asking the College to nominate a delegate to the proposed conference of representatives of the Entente States to be held at Monaco after the war. Sir Bertrand Dawson was nominated.

The late Dr. Todd.

A bust of the late Dr. Robert Bentley Todd, bequeathed by the late Miss Elizabeth M. Todd to the College, was accepted.

Appointments.

Dr. James Galloway was elected a member of the Committee of Management in place of the President, and Dr. Norman Moore expressed the thanks of the College to the President for his long services on the Committee. Dr. Hector Mackenzie was appointed a representative of the College upon the Medical Board of the University of Wales in the place of Sir Richard Douglas Powell, resigned.

The Mitchell Gift.

On the proposal of the President, a committee was appointed to report upon the method of application of the sum of £500 given to the College by Mr. F. W. Mitchell, through Dr. E.

Malins, for the investigation and treatment of tuberculosis. The President nominated the following Fellows to form the committee: Dr. A. Monckton Copeman, Dr. Hector Mackenzie, Dr. Horton-Smith Hartley, Dr. A. Chaplin, Dr. J. Calvert, Dr. J. Fawcett, and Dr. E. Malins.

Announcement of Awards.

The President announced that he had awarded the Bisset-Hawkins Memorial Medal to Sir Arthur Newsholme. The Baly medal was awarded to Professor W. M. Bayliss, F.R.S.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council was held on July 26th, when Mr. Charteris J. Symonds, Vice-President, was in the chair.

Diploma of Membership.

Diplomas were issued to ninety-six candidates found qualified at the recent examinations.

Recognition of Schools.

The following schools were added to those already recognized in chemistry and physics: The Grammar School, Preston; the Intermediate Schools, Barry; the Royal Grammar School, Lancaster.

Preliminary Examination in General Education.

The regulations relating to the above were revised as follows: The Preliminary Examination in General Education must include the following subjects:

(a) English (grammar, paraphrasing, composition; questions on English history and geography).

(b) Mathematics (arithmetic; algebra, including easy quadratic equations; geometry, including the subject-matter of Euclid, books i, ii, iii, and simple deductions).

(c) One of the following languages, namely, Greek, Latin, French, Russian, German, Italian, Spanish, or Welsh. (The examination must include grammar, translation of English from unprescribed books, translation of a continuous English passage, and of short idiomatic English sentences.)

(d) A second language selected from the foregoing list or one of the following subjects, namely: Higher mathematics, experimental mechanics, chemistry, physical geography, physics, botany, biology, geology.

Court of Examiners.

Mr. F. F. Burghard was elected a member of the Court of Examiners, Mr. H. J. Waring a member of the Board of Examiners in Dental Surgery in the vacancy occasioned by the retirement of Mr. L. A. Dunn, and Mr. W. H. Dolamore was re-elected a member of the Board of Examiners in Dental Surgery.

Future Elections of Members of Council.

The Secretary reported that the new By-laws relating to the election of members of Council had been signed by the Home Secretary, the Lord Chancellor, and the Lord Chief Justice.

Donations.

The following were received with the thanks of the Council: From Mrs. A. H. Johnson, a bust by Noble of her father, the late Dr. Robert Bentley Todd, F.R.S. From Mrs. T. Gordon Stowers, a crayon portrait of Mr. Luther Holden.

CONJOINT BOARD IN ENGLAND.

THE diplomas of L.R.C.P., M.R.C.S. have been conferred upon the following candidates who have passed the final examination in medicine, surgery, and midwifery:

A. L. Abel, H. D. Apergis, R. D. Aylward, F. E. Bendix, H. R. Bickerton, J. E. A. Boucaud, A. G. Brett, E. H. Bryant, W. B. Buer, H. R. Buttery, O. C. Carter, Bodh Raj Chaudhri, W. E. Le G. Clark, A. B. Cocker, A. J. Cockkinis, E. J. Coombe, W. T. Cooper, A. J. Copeland, Dorothy T. Daintree, J. R. Dingley, Phyllis D. Dixon, H. B. Dodwell, H. W. Eddison, Constance M. Edwards, Florence M. Edwards, M. Edwards, W. Eidinow, J. S. Eloff, E. F. Fernando, Dorothy Gilford, E. H. Glenny, J. W. H. Grace, J. Hale, Joan Hardy, E. G. Harris, D. G. Higgins, K. R. Hill, Abdel Halim Hilmy, Bertha Hinde, E. T. Hoidge, J. F. Howells, J. B. Irving, Seka Marikar Mohamed Jabir, Theodora Johnston, H. C. C. Joyce, S. Kadinsky, Haji Hyderali Khan, C. H. Laver, F. R. Law, Hilda M. Lazarus, L. K. Ledger, H. M. Leete, A. G. F. McArthur, Ruby E. McBurnie, K. McFadyean, B. Maclean, N. H. S. Macleaz, W. H. Maudling, Ambadi Krishna Menon, Pathiyaveetil Narayana Menon, Palliyarallelage Don Jeronis Milapius, Farid Mohamed, H. C. Morris-Jones, Canapathy Pillai Nagamutti, M. H. Oldershaw, N. Olivier, S. W. Page, Eleanor J. Partridge, A. McL. Pickup, W. E. Powell, S. H. de G. Pritchard, Marianne O. Ramsay, S. Riddiough, Sophie S. Rosenberg, H. Rowan, Khurshedjee Jamsedjee Rustonjee, J. F. Ryan, S. Sacks, Ahmad Hussein Samy, T. W. Shaw, K. L. Singer, P. A. Smuts, J. R. W. Stephens, H. J. R. Surridge, R. Theron, B. Thomas, G. M. Titterton, D. J. Valentine, J. A. van Heerden, José Victoria, G. H. Ward, F. W. A. Watt, R. E. S. Webb, J. de S. Wijeyeratne, A. P. Wyatt, S. Yabluevitz, G. Zachariah.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have passed the final examination and have been admitted L.R.C.P. and S. Edin. and L.R.F.P.S. Glasg.

Jean M'M. Crawford, G. C. Cossar, A. G. O'Brien, W. Templeton, J. W. Morris, J. G. M'K. Macaulay, J. Michaelson, R. P. Crawford, E. A. Hamilton, C. S. Baxter, T. R. Wilson, F. C. J. Mitchell.

Obituary.

PROFESSOR THEODOR KOCHER, BERNE.

THE announcement of the death of Professor Theodor Kocher, of Berne, will be received with the deepest regret by surgeons all over the world. He had a serious illness some time ago, but had recovered sufficiently to resume some of his professional duties this spring. All through his long career as a surgeon he was ever among the first to take advantage of every advance and himself broke new ground in many directions. His practice was founded on the constant study of physiology and pathology, and his wide views over the whole field of surgery and his brilliant technique in the operating theatre had long made Berne a place of pilgrimage for the surgeons of Europe and America.

He was born in Berne on August 25th, 1841, and after his student days there spent some time in Berlin, London, Paris, and Vienna, where he was a pupil of Billroth's. He graduated at Berne in 1865, was called to the chair of clinical surgery in the University of Berne in 1872, and for forty-five years was head of the university surgical clinic there.

Professor Kocher was one of the last survivors of the pioneers of ovariectomy, and consequently of abdominal surgery as now understood and practised by surgeons all over the world. From a note contributed to this JOURNAL in 1882 (vol. i, p. 114) on ovariectomy in Switzerland, founded on material supplied by Sir Spencer Wells, it appears that the first ovariectomy undertaken in that country was performed by Wells. It was successful, and the operation was soon afterwards undertaken by Kocher, Reverdin, and other Swiss surgeons, but it is added that until Kocher and two or three other experienced operators began to insist on the importance of antiseptics in ovariectomy the results were not favourable. Afterwards the statistics showed marked improvement in the experience both of Kocher and himself, and of other Swiss operators, but it was stated in the article from which we have quoted that Professor Kocher then "had the advantage of greater experience in ovariectomy than can be claimed by any other Swiss surgeon." Kocher, in fact, established ovariectomy in Switzerland as a practicable and justifiable operation. He developed, like his British contemporaries, into a surgeon learned and skilled in more general abdominal work, and devised contrivances, such as clamps, of high value to the operator.

Kocher wrote on many subjects, including gunshot wounds. He was the author of a textbook of operative surgery, which was translated into French, English, Italian, and Russian. A subject with which his name will always be associated is the operative treatment of goitre, and he was among the first to recognize, in 1883, the condition of cachexia strumipriva following on total extirpation of the thyroid.

We are indebted to Sir BERKELEY MOYNIHAN for the following appreciation of Kocher's work and influence:

With the death of Kocher the world loses its greatest surgeon. He lived a long life of unceasing industry, he covered a wider range of subjects than any living surgeon, and all his work was marked by clear insight, profound thought, accurate and well-ordered statement, and wise judgement.

From his earliest days he was a sound anatomist. The first of his contributions to surgery to attract attention was that in which he worked out the method now known by his name for the reduction of a dislocated shoulder. On one memorable occasion, when he sat among the audience in Billroth's theatre, a case of old unreduced subcoracoid dislocation of the shoulder was brought in. Every method of reduction was tried and failed, and efforts were at last abandoned, when Kocher, who had just perfected his own procedure, asked to be allowed to try it. Billroth consented and the shoulder was at once replaced. Kocher, being asked, went on to describe the usual position of the rent in the joint capsule, the direction of movement of the head of the humerus as it escaped from the joint, and the final positions in which it might lie. He then showed why the manipulations which he proposed were sure to succeed if duly carried out, in the ordinary case.

Throughout a long life Kocher's devotion to anatomy and his operative work on the cadaver were unceasing. There were few days, in summer or winter session, when he did not visit the *post-mortem* room to demonstrate an old operation or try a new one. His book on operative surgery gives plain evidence throughout of his easy familiarity with the anatomy of every part.

Quite early in his career he realized the truth and the vast scope of Lister's teaching. In 1875, or earlier, he introduced the operation for carcinoma of the tongue, in which, for the first time in an operation upon the mouth, a strict attention to antiseptic principles was made essential. In later years Kocher himself abandoned this method in advanced cases for that which generally bears the name of Syme. His freedom from prejudice for his own intellectual progeny was shown also in his frequent choice of other methods than his own for the radical cure of hernia. The method he devised was excellent, and indeed, when first introduced, was almost universally acclaimed as the best; yet many surgeons who visited him saw Bassini's method practised more often than his own.

Kocher's name throughout the world was perhaps chiefly associated with his work on the thyroid gland. His contributions to our knowledge of the diseases of this gland and their treatment are of course unrivalled, and he has probably left little or nothing for anyone else to say. His operations numbered many thousands, and as occasions for a scrupulous and minutely careful technical display they were unsurpassed; every tiniest detail was arranged, every difficulty most gently overcome; there was no haste, no untidiness, no shedding of one drop of blood that could be spared. Infinite accuracy, infinite care, infinite patience, gave him results as near to absolute perfection as it is possible for surgery to go. As one retraced, in afterthought, every stage in a difficult and tedious, and perhaps prolonged operation, it seemed impossible to find a fault or to discover where anything could go wrong. From the treatment of the simple cumbersome tumours of the thyroid he was led to the study of Graves's disease, and was the first to urge, and with increasing success to practise, the surgical treatment of this condition. No one who saw him operate in a case of severe Graves's disease would ever forget his tender care, his exquisitely gentle touch, and the deft, light movement of every finger. When everything was finished, the stainless towels round the wound failed to reveal the fact that an operation had taken place. Such an operation—indeed, every operation Kocher ever did—was a supreme exhibition of what perfect anatomical knowledge, a blameless aseptic conscience, the most practised technical efficiency, unflinching courage, unruffled calm, and the most exquisite gentleness could accomplish. Many of the great surgeons of to-day will frankly admit that in all these things Kocher taught them more than any other man. He was a slow operator, but there was never a moment wasted. To do an operation as he thought it ought to be done time was necessary. Those who were privileged to see his patients, in his private clinic or in the public hospital, will agree that no patient suffered from such an expenditure of time as Kocher found necessary. His whole work demonstrated the folly of those who operate with the single desire for speed. His method was the perfect one. He never wasted an instant; he never had to hurry; everything fell out according to plan, and the most sensitive tissue could hardly have been conscious of anything but a caress.

His literary work was amazing in quantity and in its high value. He published many years ago his work on diseases of the male generative system, which younger surgeons have too soon and too easily forgotten. His books on diseases of the spinal cord and on cerebral compression displayed his capacity for the most laboured inquiry into the details of difficult problems or cases and for original experimental work of the highest order.

His work in almost any department of surgery would alone have made him a reputation as a surgeon of great gifts. He devised methods, whether entirely new, or wise sound and timely modifications of older methods, with amazing fertility, for operations upon the lungs, the stomach, the gall bladder, the intestine, upon hernia, upon cranial nerves, and so on. He invented instruments and appliances innumerable—tables, scissors, clips, clamps, screens, and towels. These were mere incidents in his daily work. Every artist must have the right instruments

for his handicraft. Kocher's new methods, practised for new conditions, required new implements, and he was not slow to design them.

As a teacher he was greatly painstaking, diligent, and earnest. For two hours, 8 to 10 a.m., in the sessions he would teach in the theatre. Cases were brought in, examined and discussed. Some skill as an artist helped Kocher to make his teaching easy to acquire. He was never impatient with an honest, if stupid, effort; his voice grew high pitched and querulous when a student would try to deceive him with a clumsy bluff.

His life was one of unceasing activity. He began work early, teaching and operating at the hospital nearly every morning, and occupying the afternoons either in his private clinic, or in his study, going with great labour through the careful records of his cases.

What is the chief legacy a surgeon leaves behind him? Personal reputation however exalted is soon forgotten, and the name of a distinguished surgeon may not be long remembered even in his own country. Books which at the time of their appearance are striking in new thoughts, or in the fresh presentation of old ones, cease soon to be read. Even in the long survivors new editions change not only their contents, but perhaps the title also. The spoken word, whether by the bedside or in the theatre, is apt to slip from the memory or to be imperfectly recalled. A few characteristic sayings may chance to be handed down, but their authorship is soon lost. Wealth is, of course, rarely attained by any member of our profession, and for itself has happily no value among us.

The chief legacy which a surgeon can bequeath is a gift of the spirit. To inspire many successors with a firm belief in the high destiny of our calling, and with a confident and unwavering intention both to search out the secrets of medicine in her innermost recesses, and to practise the knowledge so acquired with lofty purpose, high ideals and generous heart, for the benefit of humanity—that is the best that a man can transmit.

Though Kocher trained no great men in his own school, as Billroth did, there are surgeons all over the earth who can say that in larger or smaller measure it is their pride to claim some humble share in this great inheritance, which Kocher, above all others, has nobly bequeathed to them.

To Lieut.-Colonel LYNN THOMAS, C.B., C.M.G. (Cardiff), we owe the following personal note:

By the death of Professor Kocher, one of the outstanding modern masters of surgery has been removed. He was undoubtedly one of the great makers of surgery of the nineteenth and twentieth centuries. I had the great privilege of knowing him for over twenty years, and during a visit he paid Cardiff and South Wales I had the opportunity of realizing how many interests he had in life apart from that of surgery.

As a surgeon he was unsurpassed in the observance of detail in technique, and during the many visits I paid to his operation theatres at the Inselspital and his private hospital I never saw a single occasion upon which one could criticize adversely, or went away with a feeling that somebody else who had specialized in departmental work could have done the work he had in hand in a more masterly fashion. I have seen surgeons on the Continent and in America who could operate with more speed, but I have never seen one whose judgement was so sound in the performance of daring operations where risk to life arose. He had one speed, which I designated the "Kocher speed"; it was uniform whether he performed the simplest or the most complex operation, either upon the extremities, the abdomen, the neck, or the brain. There is hardly a branch of modern surgery in which he has not left a valuable and permanent impress, but his name will always be connected with a revolution in the treatment of goitres, and as an illustration of the amount of work he did in this department alone I may quote from a letter I received from his son, Albert Kocher, dated March 12th, 1912, the following sentence: "My father yesterday performed his fifth thousandth goitre operation."

I have never seen him use spectacles for operations, and in talking this matter over he said that Nature had been very good to him in giving him two eyes, the one for the enthusiasm of early age, and the other for the maturity of

vigorous but advancing years. He had an extraordinary energy for work, and I have seen him working from 8 o'clock in the morning until 1 o'clock at the Inselspital, then in the afternoon perform three thyroidectomies for Graves's disease (upon a Russian, a German, and an American) at his private hospital, and afterwards pay visits and hold consultations, and turn up at 8 o'clock in the evening to dinner without any appearance of fatigue. He had an old-world courtesy, and in his home circle was always affectionate, pleasant, and humorous. The last occasion on which I visited Berne was in June, 1914, and at that time he was as alert and as keen in his work as he was the first day I met him.

Surgery all over the world has lost a great figure by the death of Professor Kocher, and it is pleasant to record that in his own native town, so dear to him and Mrs. Kocher, his genius was long ago recognized; one of its main streets is designated by his illustrious name.

We learn that the death of Captain IAN MACFARLANE, M.B., Ch.B. Edin., R.A.M.C., announced last week (p. 131), was due to typhus fever. Soon after graduating in 1911 Dr. Macfarlane went to assist Dr. Scrimgeour, who was in charge of the Edinburgh Medical Missionary Society's Hospital, Nazareth. After some two years there, during which he had a very severe attack of typhoid fever, he was, when the war broke out, on his way to assist Dr. Mackinnon at Damascus. Returning to this country in August, he acted for a time as resident surgeon in the Edinburgh Royal Maternity Hospital. He then volunteered for service at the front in connexion with the R.A.M.C., and was sent for more than a year to France. Great was his joy when he was transferred to Egypt, in April, 1916, and foresaw an opportunity of making use of his knowledge of Arabic and of getting near again to the sphere of his former work in Palestine. In a brightly written letter of June 28th he spoke of his work in charge of a hospital for military labourers and of a typhus isolation camp as well as a camp for refugees. It was doubtless through the service he was thus so freely rendering that he fell a victim to the fever which proved fatal. Captain Macfarlane had a particularly winning nature, and was devoted with his whole strength to the medical missionary work to which he had dedicated his life. A memorial service was held at Juniper Green on Sunday, July 29th, at which Colonel C. W. Cathcart, Dr. J. W. Ballantyne, and Dr. James Ritchie spoke.

Medical News.

THE London Insurance Committee, on July 24th, appointed Dr. Noel Dean Bardswell, M.V.O., to be medical adviser for sanatorium benefit to the committee in place of the late Dr. J. E. Squire.

THE honorary secretaries of King Edward's Hospital Fund for London have received at the Bank of England the sum of £35,000, being a contribution from a donor who desires his gift to be so acknowledged.

MISS EILEEN PEEL has been appointed head of the National Hospital and University College Hospital School of Massage and Electrical Treatment, Queen Square, London, W.C.1, which will open in October next.

FROM January 1st to June 16th the cases of cerebrospinal meningitis in London of which information was received numbered 307 (including 10 military cases) with 164 deaths. The number of cases notified during the same period last year was 295.

THE temporary permission granted to persons engaged on July 28th, 1916, in the bona fide practice of dentistry, but not registered under the Dentists Act, to purchase preparations containing not more than 1 per cent. of cocaine for use solely as local anaesthetics for dental work, has been extended by the Home Secretary until further notice.

AT an inquest at Hull upon a man who had died after taking 2 oz. of supposed barium sulphate in bread and milk prior to x-ray examination, the evidence showed that tartar emetic had been supplied by the pharmacist in mistake. The bottle was labelled "barytae sulphas," and the pharmacist stated that the label must have been incorrectly applied by someone at least thirty years ago. He could not recall any previous order for barium sulphate

during the past forty years, which would explain why the mistake had not been discovered. The jury found that death was due to misadventure.

The American Electrotherapeutic Association proposes to form a unit to furnish facilities and men to carry out the treatment by electrotherapeutic and other physical means of various war injuries, including, among others, delayed repair, sprains, contusions, atrophies, arthritis, and neuritis. Its equipment, which it is intended shall be provided by subscription, will include transformers, diathermic apparatus, x-ray apparatus for therapeutic use, static machines, therapeutic lamps, sinusoidal machines, and constant current apparatus. It is hoped to obtain the recognition of the Council of Defence of the United States of America.

KING GEORGE'S Fund for Sailors has been founded to obtain fuller and more sustained support for the great marine charities of the country, upon whose resources the stress of war has made heavy and increasing calls. These charities minister to the needs of sailors of every kind, including mine-sweepers and fishermen, and their dependants. The chairman of the fund, H.R.H. the Duke of Connaught, appeals to the public for generous support at the present time, when the safety of our shores and the existence of the empire depend so largely upon the bravery, endurance, and self-sacrifice of British seamen of the navy and mercantile marine. Contributions may be sent to him, addressed to King George's Fund for Sailors, Trinity House, London, E.C.3.

At a recent meeting of the Association for Promoting the Training and Supply of Midwives, Dr. E. W. Hope, M.O.H. Liverpool, gave an address on the best means of increasing the supply of practising midwives. The need for the midwife, he said, was not likely to diminish in view of the shortage of doctors, the lack of maternity homes—to-day whole counties were without a single maternity hospital bed—and the large increase in the birth-rate which would follow the war. The intending midwife should find it possible to gain a longer and more adequate training at smaller cost to herself. He suggested that after an entrance examination to test the general fitness of the candidate, free or subsidized professional training for perhaps two years if necessary should be provided by the State. At the close of the training a professional examination would give evidence of fitness to practise. The small pittance which the patient in many cases was only able to afford should be made up by a Government contribution to not less than a guinea for each birth attended. He believed that this guarantee could be given and safeguarded from imposition. One advantage of such a system would be the supervision of midwives direct from a Government department. Such a scheme, he thought, would cost something like £80,000 a year.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

THE telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are: (1) **EDITOR** of the *BRITISH MEDICAL JOURNAL*, *Aditology, Westrand London*; telephone, 2631, Gerrard. (2) **FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate, Westrand London*; telephone, 2630, Gerrard. (3) **MEDICAL SECRETARY**, *Medisecra, Westrand London*; telephone, 2634, Gerrard. The address of the Irish Office of the *British Medical Association* is 16, South Frederick Street, Dublin.

The address of the *Central Medical War Committee* for England and Wales is 429, Strand, London, W.C.2; that of the *Reference Committee of the Royal Colleges* in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the *Scottish Medical Service Emergency Committee* is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

QUERIES.

INCOME TAX.

W. A. S. R. explains that he has recently obtained repayment of income tax for 1916-17 in respect of "small income relief," and inquires whether a similar claim can be made for 1915-16.

*. Our correspondent does not state the amount of his total income for 1915-16, and a categorical answer cannot therefore be given. It may, however, be sufficient to say that for 1915-16 there was no "small income relief" where the total income exceeded £500, and that it was comparatively small even where applicable.

LETTERS, NOTES, ETC.

THE Oxford University Press has published a biography of Ingram Bywater, one time Regius Professor of Greek in the University and for thirty-five years an active member of the board of the Press and a diligent contributor to the great dictionary. The *Periodical* for July quotes from the biography some of his sayings. Once in reply to a remark on the lack of interest in scientific research displayed in general society, Bywater said, "The desire to know the reason of things is quite exceptional, and always has been. Plato said that philosophers must always be few." Another saying was that modern education seemed to be "a conspiracy on the part of schoolmasters and dons to keep men babies until they are four-and-twenty." Having gone so far we may be excused for quoting a story he used to tell in defence of his own habit of smoking. "Pio Nono, when in conversation with Cardinal Antonelli, lit a cigarette and handed the case to the Cardinal, who said, 'You know, Holiness, that I have not that vice.' 'You know, Eminence,' replied the Pope, 'that if it were a vice you would have it.'"

THE ROWAN BERRY: A TOPICAL SIALAGOGUE.

DR. JOHNSON SMYTH (Bournemouth) writes: Rowan berries are very plentiful just now. I can find no record of their use as a sialagogue, yet they act as such most powerfully. I found this out by accident when suffering from enteric fever thirty years ago. Can anyone inform me as to what the acid or other constituent is that acts so promptly?

A TOO-PUNGENT MOUTH-WASH.

H. W. writes to confirm from his personal experience the opinion that an aqueous solution of thymol is not a suitable mouth-wash for daily use. A saturated solution caused intense smarting; it was considerably diluted, but after two months the gums were tender and bled when brushed, and there was slight marginal ulceration. The teeth were sound and the gums previously healthy. On discontinuing the mouth-wash the condition cleared up in about a week.

STATUS LYMPHATICUS.

DR. JOHN HADDON (Denholm, Hawick, Scotland) writes, with reference to Dr. Cameron's contribution to the *JOURNAL* of June 9th on status lymphaticus, to suggest that he should, in the treatment of such cases, confine them to one food at a time so as to be sure of its action one way or another. We know, Dr. Haddon continues, more now about the physiological action of drugs than we do about that of foods. I find that each food has not only an action on the several emunctories, but gives rise to some special symptom. Dr. Cameron blames carbohydrates generally, but I find that the several cereals have different effects on the emunctories. Wheat causes not only intestinal, but renal stasis, and throws a strain on the skin and lungs. I also find that each cereal seems to have some injurious item, and that a mixture of cereals is especially bad, the combined bad item having more effect.

THE PURITY OF FOOD.

DR. ARTHUR T. TODD-WHITE (Leytonstone) writes: I would venture to suggest that if a great and important department such as a Ministry of Health is created it must do more than co-ordinate existing work. It must be responsible for maintaining the health of the people in every way. The proposals of the Association deal principally with the cure and prevention of disease. I am of opinion that the first and most important duty of the Ministry of Health will be to take absolute control of the food of the country; as we cannot exist without food, so we cannot keep fit and resist disease unless we are properly nourished, and at the present day (I do not refer to the war period) it is impossible to get pure food or drink; possibly in many cases the added foreign matter is harmless, but in others this is not so. The bad effect of adulterated food is in some cases obvious, and the effects immediate, but in others the deleterious effects are slight and unnoticed at the time, but gradually the system becomes badly nourished and the man or woman who should be absolutely fit finds they are "worn out." The Minister of Health should get a bill passed imposing imprisonment without the option of a fine for selling an article of food or drink knowing that article is not entirely what it is sold as. At present a man who has made thousands of pounds by selling rubbish to the public as food, gets off with a trivial fine which probably amounts to about one per cent. of the profit he has made by his swindle.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Even lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

THE INSTITUTES OF SURGERY.

AN HISTORICAL REVIEW.

BY

SIR BERKELEY MOYNIHAN, C.B., M.S., F.R.C.S.,

PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF LEEDS;
TEMPORARY LIEUTENANT-COLONEL R.A.M.C.

MEN, it is said, are apt to be taken at their own valuation. What is true of a man may be true of a nation. It is beyond dispute that Germany, as a result, in part, of the arrogant repetition of her claim to intellectual superiority over all nations, and in part, of a tolerant and sometimes disdainful silence or acquiescence by others, has been accepted almost universally as the pivot and centre of the world's thought. My own realization of this, in regard to surgical matters, was dramatic in its suddenness. I had been a student in Germany years ago, had lived with German students, and followed closely the work of German surgeons in several clinics. I had formed my own conclusions as to the value of the German contributions to surgical advancement, and nothing that has happened since the war began has altered in any way the opinions I then held. About five years ago one of the most distinguished of the Scandinavian surgeons, who had made a yearly pilgrimage to Germany of some weeks' duration, came to spend his surgical holiday in England. He lived with me for more than a month. I had always known him as a warm advocate of Germany's methods in surgical literature and practice, and of his intellectual contempt for most of the things which other nations had done. Of the work of these other nations he had learnt nothing at first hand; the little he knew had been distilled through the minds of German interpreters, and had been conveyed to him verbally on his frequent visits, or had been taken from the easily accessible German journals and textbooks. At our first breakfast meeting he told me of his immense obligations to Germany, of his schooling in her methods, of his devoted attention to the debates of the German Surgical Association; and he went on to say that he felt it almost an act of treachery to spend his surgical vacation in any other land. And then he gravely announced that "Of course all surgical advance in the last fifty years has come from Germany." To that kind of fervid unrestrained assertion the most fruitful denial is given by a questioning assent. I answered: "Of course; tell me of one." Whereupon I had to learn from him that the introduction of the antiseptic system into practice was wholly to be attributed to German research, adoption, and advocacy. Now this claim so confidently made, and, I hope I may say, so utterly shattered in the debate which followed, is precisely the type of claim which Germany herself has always made. Most of the great ideas, she tells us, originated with her; those that by chance arose elsewhere would never have come to fruition but for her acceptance, and for the authority with which thereby they were endorsed.

ANTISEPTICS.

Of the facts as to the discovery of the antiseptic system there is, of course, no dispute. They begin with the discovery in 1836 by Latour of the living character of the yeast cells by which fermentation was produced. This discovery, it is interesting to recall, was denied both by Liebig and by Helmholtz. The confirmation and extension of this work by Pasteur in 1856 showed that putrefaction and fermentation were the result of living particles, and that for each type of fermentation a specific particle was necessary. "The most far-reaching of my researches," said Pasteur, "is simple enough; it is that putrefaction is produced by living ferments." He asserted that the oxygen of the air was not the cause of putrefaction, as every one hitherto had supposed; that, indeed, some of the causes of decomposition could thrive only in the absence of oxygen. This observation, too, which distinguishes "aërobic" from "anaërobic" organisms, is of the first importance. It was these discoveries which suggested to Lister the thought that the putrefactive changes in wound discharges might be due to living organisms, and that the exclusion of these would enable wounds to heal without the formation and corruption of purulent discharges.

In 1867 Lister wrote: "When it had been shown by the researches of Pasteur that the septic property of the

atmosphere depended, not on the oxygen or any gaseous constituent, but on the minute organisms suspended in it which owed their energy to their vitality, it occurred to me that decomposition in the injured part might be avoided, without excluding the air, by applying as a dressing some material capable of destroying the life of the floating particles."

A discovery is rarely the work of one mind. It is one observation added to another that makes the super-saturated solution from which the crystal of truth at last precipitates. Lister never ceased to give credit to Pasteur for his share in the work that led finally to the development of the antiseptic method. The exploratory work, the pioneer work, all that was original, was done therefore by a French observer and an English surgeon. The exploitation of this work, it is true, was almost at once eagerly and widely carried out by the surgeons of Germany. The system was examined, appraised, and adopted throughout the whole empire of Germany; but so it was elsewhere. Lister never had a more ardent, a more scrupulous and conscientious pupil than Lucas-Championnière. Up to his death this veteran French surgeon carried out with meticulous care exactly those procedures which he had learnt from Lister. But the loud shouting in support of the antiseptic treatment came chiefly from Germany. When in 1875 Lister visited that country his progress was a triumph. It is notorious, however, that in carrying the Listerian principles to their logical conclusion in practice, Germany fell far behind other countries. In recent times has any surgeon visited Germany to learn a good technique? Is it not true to say that those surgeons of whom one heard most in the world, great teachers and writers as they doubtless were, were lacking in the very rudiments of a sound and careful method? There was not, I truthfully believe, one surgeon in the whole German empire who looked upon an operation as an experiment in bacteriology, and who to avoid infection in his wounds used scrupulous care in the preparation and manipulation of his instruments and materials, who avoided chance contamination, and who used extreme gentleness and delicacy of touch as modes of avoiding that form of trauma which makes infection easy. And the average display of a technique called aseptic or antiseptic was something immeasurably below the standard of some surgeons in England and of many in America. Even in the method they so ardently exploited, and in a field they claimed as their own, they fell far short of the best. This example is typical of many. All modern surgery, as we know, dates from Lister. The difference between the surgery of ancient days and the surgery we practise to-day is expressed in one word, "Lister."

Of all the advances made in surgery the most fruitful and the most interesting is that which depends upon a study of the "pathology of the living." Lister made it possible to operate with safety upon conditions which threatened life, or made it almost unendurable—such, for example, as ovarian cyst. And by degrees, as methods were perfected and experience widened, other diseases could be attacked, at first in their terminal or more dramatic manifestations, as in the perforation of gastric or duodenal ulcers; and later in their pathological career as disturbers of function or of health, before the later complications had had time to develop. It is interesting to note that the first surgical attack upon many diseases afflicting the abdominal viscera has been made when terminal events have rudely developed, and when therefore the surgical hazards were greatest. It was only in later days that the deliberate operations for initial stages of the same disease were brought within the province of the surgeon.

THE APPEAL TO NATURE.

When we review the wonderful and varied achievements of medicine it is not easy to fix a time at which the science and the art of surgery, as we think of them to-day, began to develop. As we look back we realize that it is because of the work of Vesalius the anatomist, of Harvey the physiologist, of Morgagni the father of pathology, and later of John Hunter, the first of scientific surgeons, that all subsequent advances were made possible. From the rude efforts of the early and mediæval surgeons the first real step forward was made by Ambroise Paré, who stands conspicuous above all his contemporaries at the time of the Renaissance. Between Paré and Hunter probably only one surgeon was of serious consequence in the progress of our

art. This was Richard Wiseman, a man "given to the observation of nature," who was the first to advocate and practise primary major amputations. Till the days of Hunter surgery produced, it is true, great or successful individual practitioners, but there was little or no progress in the scientific work upon which the craft must always be based.

It was Hunter in England, and Bichat in France, who went to original sources for their knowledge. Hunter wrote of himself, "I am not a reader of books," and "I believe nothing I have not seen and observed myself." His prodigious industry, his intellectual rapacity, his vast store of first-hand observation, and his simple attitude as a student all his life, are not equalled in the history of Medicine. Harvey had said of himself that he felt it in some sort criminal to call in question doctrines that had descended through a long succession of ages and carried the authority of the ancients, but he "appealed unto Nature, that bowed to no antiquity, and was of still higher authority than the ancients." With Hunter it was quite different. His eager inquiry was always for the story as it was written by disease upon the tissues of the dead body. His information was always first hand, gleaned from every source, with unwearied patience and untiring zeal. His disregard of written words and of ancient authors was deplorable no doubt, but a striking and authentic characteristic nevertheless. His reply, when taunted with ignorance of the classics, is famous: "Jesse Foot accuses me of not understanding the dead languages, but I could teach him that on the dead body which he never knew in any language, dead or living." He was the born collector, possessed of an insatiable appetite for knowing rather than wondering, and for seeing rather than reading or hearing of another's work. No man ever suffered less from the tyranny of the written word; no man ever searched more diligently or in humbler mood for those eternal sources of the truth upon which alone a science of medicine can be founded, and from which alone it can be continually refreshed. Hunter realized, as Paré and Franco before him had done, as every great original thinker since has done, that the foundations of true progress in scientific work are laid deep, that it is "from the depths, not from the heights, that medicine is fed; from the springs, not from the sky." The impetus and the authority given to surgical work by the researches of Morgagni, of Bichat and of Hunter were incalculable. The time was gone for ever when a pure and dangerous empiricism could be practised; surgery became a rational procedure, and its new ventures were held in restraint, as we now realize, only by the fear, or rather the certainty, of inflammatory complications more immediately dangerous than the disease from which relief was sought.

For the groundwork of medicine and of surgery, therefore, Germany was in no degree responsible. It was Vesalius of Brussels who laid solid the foundation of anatomy, in a treatise remarkable alike for the accuracy of the descriptions and for the beauty of the illustrations, which came perhaps from the studio of Titian. It was Harvey, our own countryman, who, by his immortal discovery, swept away the decaying fragments of Galenism, and made possible all later researches in physiology. It was Morgagni, the Italian, who brought together the statics and dynamics of medicine, who founded pathology, the science of the causes of error in the working of the human machine, and who explained symptoms by assigning them to structural alterations in the several organs of the body. It was Hunter who changed surgery from a handicraft to an art based upon an accurate knowledge of diseased tissues, who first made of surgery a science. It was Pasteur, the Frenchman, who guided Lister to his discovery of antiseptic surgery, which has changed the whole history of our science and craft. It was Morton and Warren of Boston, and Simpson of Edinburgh, who, by the discovery of ether and of chloroform, robbed surgery of its agony and horror and made it accessible as well as possible. To all these weighty matters, to all the indispensable achievements without which medicine could have made no advance, it is the simple truth to say that Germany gave nothing.

ABDOMINAL SURGERY.

The first great surgical adventure of modern times was concerned with the removal of ovarian cysts. The history

of ovariectomy is well known, but will bear at this moment a brief repetition. Removal of the ovaries in animals and in aborigines has been practised from prehistoric times. In the literature of the middle ages several curt references were made to "dropsical ovaries"; and opinions were expressed that operative measures might sometimes be undertaken with a remote chance of cure. The first successful case was operated upon in 1701 by Houston of Glasgow; the patient lived till 1717. John Hunter wrote in 1785: "I cannot see any reason why, when the disease can be ascertained in an early stage, we should not make an opening into the abdomen and extract the cyst itself." Before this William Hunter had written, in 1762: "It has been proposed by modern surgeons, deservedly of the first reputation, to attempt a radical cure by incision or suppuration, or by excision of the cyst." The first surgeon, however, to whom the world's credit and applause are due for establishing the operation as a proper and safe procedure was McDowell of Kentucky, an old pupil of John Bell in Edinburgh, by whose teaching he was inspired. McDowell's first case was operated upon in 1809; the patient lived till 1814. Between 1809 and his death in 1830 McDowell operated upon ovarian tumours in thirteen cases, and it is known that eight patients recovered. After his day the operation fell into disrepute, and the failures were so many that Baker Brown abandoned the operation, saying: "It was of no use, peritonitis would always beat one." It was after his return from the Crimea that Spencer Wells, an old pupil of the Leeds Infirmary, upon his appointment to the Samaritan Hospital, began, in 1858, that series of operations which firmly established the surgical treatment of ovarian tumours in favour, and by its success, and by the influence it had upon the treatment of other intraperitoneal conditions, opened up the whole field of abdominal surgery. The opposition to the surgical treatment of ovarian cysts was, as is well known, of the most bitter and inveterate kind, but Spencer Wells, by his simplicity of character, his unwavering integrity, and his sweet reasonableness in argument, wore down all antagonism. In the year 1880—that is, in twenty-two years—he had operated upon 1,000 cases, of which 768 recovered. During the first five years one patient died in every three operations; in the last two years one patient died in every ten. Writing in 1882 Spencer Wells said, "In Germany until quite recently ovariectomy was scarcely talked or thought of." Billroth, in a lecture on ovariectomy, said of Spencer Wells, "I shall willingly regard myself during my lifetime as his scholar." It is astonishing to recall that Spencer Wells's early success was achieved before the introduction of antiseptic surgery. In the edition of his work on *Ovarian and Uterine Tumours*, published in 1882, he endeavoured to estimate the difference in the mortality and morbidity of his cases as a result of the introduction of Lister's methods. It is therefore true to say that the whole of the immense progress that abdominal surgery and internal medicine have made in the last thirty years has been due to the impulse and the investigations of these two English surgeons, Spencer Wells and Lister. In all the pioneer work which made possible the infinite achievements of modern abdominal surgery, the contribution of Germany was precisely nothing. What part has she played in the later progress?

Let us take for a first inquiry the surgery of the gall bladder. The fullest account of the history of this extraordinarily interesting adventure in surgery is given by many German authors, of whom Langenbuch is, perhaps, the chief. On page after page of the story as told by him reference is made to the priority of German surgeons, and pride in German achievements is openly and frequently expressed. A chapter of this author does duty not only as a contribution to the history of surgery but as a political pamphlet also. And, like much in the literature of politics, it is found on close examination to be acutely controversial, when it is not false. What are the facts? The first attempt to deal surgically with the gall bladder was made experimentally by Zambecari in 1630. This observer ligatured the cystic artery and duct in a dog and removed the gall bladder. Two months later the dog was killed, and to the ligatured stump omentum and small intestine were found adherent. To Jean Louis Petit in 1743 is to be attributed the first suggestion of the surgical treatment of a distended gall bladder, and the first considered attempt to deal operatively with it during the life of the patient. Over a century later, in 1859, Thudichum, in a paper on

the "Pathology and treatment of gall stones," wrote: "In decided cases the surgeon should consider the propriety of planning and performing an operation for the extraction of these foreign bodies either in a direct manner or by forming a biliary fistula and adopting a lithotriptic proceeding." In 1876 Thudichum and Maunder again broached the subject, and in 1878 Handfield Jones also proposed operation to a patient suffering from cholelithiasis. In the year 1867 an American surgeon, Dr. Bobbs, operated upon a case of abdominal tumour, diagnosed as probably one of ovarian cyst. The tumour proved to be a gall bladder, upon which Bobbs performed "lithotomy," removing several stones. But it is to Marion Sims that the credit is to be given for the first formulation of the operation of cholecystotomy; the deliberate planning and the practical accomplishment of a procedure so carefully designed and so thorough that Lawson Tait wrote, "The entire possibilities of the treatment of gall stones and distended gall bladder are exhausted in Dr. Marion Sims's original paper."

The first operation successfully performed in two stages is to be credited to Kocher, who in 1878 opened the abdomen, packed round the gall bladder with Lister's gauze, and six days later, when a barrier of adhesions had formed, opened the gall bladder and emptied it of stones.

An examination of all the lengthy literature of this subject, however, leaves one in no doubt that the most conspicuous merit for the pioneer work attaches to Lawson Tait. It was he who, basing his work upon the case of Marion Sims (a case of common duct obstruction, with jaundice, which proved fatal in a few days from haemorrhage), made of cholecystotomy a safe operation. Probably no operation of equal difficulty and severity was ever ushered into the world with so marvellous a series of successful cases. In 1884 Tait wrote: "I have performed the operation thirteen times, and all recovered." Up to the end of 1884 there had been performed in all the world twenty-eight operations, of which Lawson Tait did thirteen. Of the first 104 cases, he had operated upon 56; the whole of Germany then claimed 9 cases.

Cholecystectomy, the safe possibility of which had been shown experimentally two and a half centuries before, was first performed on July 15th, 1882, by Langenbuch. This is a very valuable addition to the resources of the surgeon, and its originator may well have had a legitimate pride in its inauguration. We cannot, however, hope to pay to his memory the luscious compliment he paid himself in the arrogant Prussian fashion and at inordinate length. If it is the only original contribution of Germany to the surgery of the biliary system, it is in truth a considerable one.

In the later developments France, England, and America may claim that they have played the greater part. To them are due not only those advances along the frontier of medicine which have disclosed to us the early symptoms of cholelithiasis, but also those technical perfections which have made precocious interference the safest and most prudent of all modes of treatment. Over against this recent work what has Germany to show? She has one man of large experience to put forward—Kehr, and he is, indeed, a typical representative of his country. Kehr has been a prolific writer and has published very full accounts of his technique and results. Kehr advises operation where there is obstruction of the cystic duct, infection of the gall bladder or ducts, or when stones are arrested in the common bile duct. A great many of the indications accepted by surgeons in other countries are omitted. For the purpose of access to the parts he has devised an incision, the *Wellenschnitt*; of great length, it begins in the epigastrium below the ensiform cartilage, extends downwards towards the umbilicus, then across the right rectus transversely for 2 in., and, finally, vertically down the rectus for 3 in. to 4 in. A very free exposure results. In all cases, or almost all, the gall bladder is removed, and the hepatic duct drained, often by a tube of T-shape, one arm of which goes upwards to the liver, the other downwards to the duodenum. The methods throughout are crude, coarse, heavy-handed, lacking everything in the way of daintiness and refinement. This is expressed in the results, in which the mortality and morbidity are excessive. So far as the purely intellectual side of the work is concerned, in all Kehr's writings there is nothing at first hand. The

inquiry as to the inaugural symptoms of cholelithiasis, the question of the early recognition of the presence of stones, the association of gall stones with other abdominal diseases, appendicitis, intestinal stasis, in the relation of effect and cause—of these matters there is rarely an original observation. There is the same academic completeness of exposition which we find in all German work; full, indeed tedious, accounts of anything and everything wearisome prolixity; but the facts and records are there in full. The only original piece of work done in the whole realm of cholelithiasis, in recent years in Germany, is that upon the formation of gall stones, by Aschoff and Bacmeister; it is important and accurate, but it touches only the fringe of the larger question of cholesterinaemia, in which the chief work has been done by the French.

What is the history of the surgery of the stomach? The earliest account of gastric ulcer was given by Matthew Baillie in 1793. It is true that the disease is mentioned both by Galen and Celsus, and that there are records of probable cases, when haemorrhage or perforation occurred or fistula into the stomach developed, as early as the sixteenth century. But the first clear and illustrated anatomical description, accompanied by clinical histories, was given by Baillie. It is, however, to Cruveilhier, who wrote in 1829 and 1830, and up to the year 1838, that we give credit for the first full and accurate descriptions of the pathology and clinical manifestations and treatment of this disease. These descriptions are in the tenth and twentieth parts of his splendidly illustrated work on pathological anatomy. To Cruveilhier the famous German physician Ewald attributed the first careful and comprehensive description of gastric ulcer, and said that he "was the first to raise the gastric ulcer from a curiosity of the autopsy table to the dignity of a definite and recognizable pathological condition." In the year 1835 Cruveilhier gave the first suggestion of the development of cancer from a simple ulcer.

The earliest records of duodenal ulcer are found in connexion with stray cases, or in those where perforation or haemorrhage had occurred and caused death. The earliest mention was by Travers in 1817. Abercrombie in 1830 gave the first connected account of the disease, and recorded a few cases. In 1894 the first successful case of operation for a perforated ulcer was recorded by H. P. Dean of London. In 1900 Weir of New York gave an excellent summary of all the cases of perforation then on record. But of duodenal ulcer as a cause of continued or recurrent dyspepsia, or as a pathological lesion to which were attached a series of symptoms capable of recognition during life, there is nothing. The first ascription of a group of symptoms to the definite structural lesion in the duodenum is to be placed to the exclusive credit of English medicine.

The development of the surgery of the stomach has been one of the most brilliant and most fascinating of all the recent conquests of our art. So long ago as 1810 it had been shown by Merrem that the removal of a part of the stomach in dogs could be followed by recovery. This experiment was repeated and multiplied in 1876 by Gussenbauer and Winiwarter. It is, however, to a French surgeon, a most dexterous operator, that the credit is due for the first attempt, albeit unsuccessful, to remove a part of the stomach for cancer. On April 9th, 1879, Péan of Paris carried out the first pylorotomy for malignant disease. The operation was repeated, again with a fatal result, by Rydygier in 1880. It was on February 8th, 1881, that Billroth in Vienna performed the first successful gastric resection for carcinoma. I have seen the specimen, which consists of the pyloric end of the stomach; it measures about 3 in. in length in its present state. It was the work of Billroth and of his assistants Mikulicz and Wölfler that proved the surgical treatment of carcinoma of the stomach to be feasible. Billroth clearly laid down the principles and the technical details to be observed in all gastric operations. All later work was made possible by his work, and we may safely reckon his contribution to this branch of surgery as the finest of the many notable achievements in the life of this great surgeon. It fell to Wölfler, while assistant to Billroth, to perform the first operation of gastro-enterostomy, on September 27th, 1881. The patient suffered from a malignant obstruction of the pylorus, and it was Wölfler's intention to perform resection. This was found impossible, and the abdomen was about to be closed when Nicoladoni, who was assisting, suggested

that the jejunum should be united to the stomach and an opening between the two viscera made to relieve the pyloric obstruction caused by the growth. The original operation was of the "anterior" type. Union of the jejunum into the posterior surfaces of the stomach was first suggested by Courvoisier of Basle, and von Hacker of Innsbruck.

The great surgical accomplishments in the last quarter of a century have been concerned with the simple diseases of the stomach, with chronic ulcer and its complications. The first gastro-enterostomy for chronic obstructive ulcer was performed in 1892 by Doyen of Paris. It is to the advocacy and to the marvellous technical skill of this surgeon that we must attribute the general recognition of the value of surgical measures in cases of chronic gastric disease and the recognition of gastro-enterostomy as a "drainage operation." The surgery of perforating ulcer of the stomach began with Mikulicz, whose first suggestion dates from 1880. Between the years 1885 and 1893 Mikulicz operated upon thirty-five cases with thirty-four deaths. This is to be considered, taking into account the early period of this work, as the saving of one life, rather than the loss of many.

The literature emitted by Germany upon the subject of gastric diseases is vast in quantity, prolix and turgid in style, lacking insight and interest, and almost utterly devoid of inspiration or original thought. It is, however, a complete record of the progress made and of the knowledge gained by all the workers in every corner of the field. The Germans are seen in their most characteristic phase as gleaners and harvesters. The seed has been sown by others; it is they who have guarded the crop, garnered it, gleaned every straw of it, and stored it in vast and ugly chambers. Gastric ulcer is a comparatively rare disease, of few but clear-cut symptoms. Around this simple matter the German clinicians have weaved a web of rhetoric which has encumbered it and swathed it beyond recognition. And they have borrowed freely from a riotous but rank imagination bereft of facts, and have insulted the intelligence of those who could not agree with them. The literature of Germany on such a subject as gastric ulcer reminds me irresistibly of Hans Andersen's delightful story of the "Emperor's New Clothes." Around this simple disease their physicians weaved, with unceasing industry, garments of a material every thread of which they declared to be of the rarest and finest quality, they told all the world of the beauty and superb texture of these royal robes; so confident and magisterial were their loud assertions and so complete the trickery by which they imposed upon all spectators, saying that only those of virtue could see the wonderful garments, that, as in the story, the crowd was humbly acquiescent. But at last the little child, the surgeon, came along and cried: "But he has got nothing on." And the whole artificial fabric was torn away, and the imperial ulcer was seen for what it was in all its naked ugliness.

SURGERY OF THE BRAIN AND CORD.

The development and progress of cerebral surgery in the last century would certainly be considered by the older physicians, could they learn of it, as the most incredible achievement of all. To them the skull and its contents were sacred and inviolable. Aristotle had spoken disparagingly of the brain, saying it was a mere cooling apparatus, and trephining operations had been not uncommon even in prehistoric times. But by the mediaeval physicians the brain was looked upon as the seat of the soul, and no profane hand might be laid upon it. When, however, the Renaissance came, with its astonishing development of physical science as well as of art, the work of Mondinus and Vesalius opened the path for all later explorers. What Harvey achieved for physiology was almost equalled by the work of Thomas Willis on the nervous system. As Victor Horsley said, these researches "exhibit an extraordinary grasp of the function (and its corresponding relation to structure) of the nervous system generally." Willis's work ought to have abolished for ever the old mystical beliefs as to the function of the brain. He was the first to allocate definite functions to distinct parts of the nervous system and to assert that the excitation of the cerebral cortex passed into the substance of the brain and thence into the spinal cord and nerves. The work of Thomas Willis was, unhappily, ignored completely,

though as we look back upon it we are inclined to agree with Horsley, who wrote "that it was due to Willis that probably the greatest advance gained in psychology ever since it became a science, the localization of function to distinct parts of the nervous system," was made. The first of those who sought by the method of experimental research to discover the secret of the functions of the brain was Flourens in 1826. His investigations dealt both with the cerebrum and the cerebellum, and were of high value, not only as examples of a new method, but also because of the positive, though limited, conclusions upon many matters, which as a result of his work he was entitled to draw. But even he, writing more than a century and a half after Willis, asserted that the brain worked as a whole, and that separate specific functions could not be allotted to its several constituent parts. Indeed, the universally accepted opinion up to the year 1861 was that the brain acted as other organs acted, its function being carried out by an equal working of all its parts. In this year Broca, as the result of his inquiries into the pathological anatomy of certain cases of aphasia, came to the conclusion that the faculty of articulate speech depended upon the integrity of a definite and limited area of the cerebral cortex. Broca's discovery was revolutionary; it involved a complete reversal of former opinions and judgements, and it opened up afresh the whole question of the function of the cortex of the brain. Hughlings Jackson in 1869 was the first to assert that the convolutions of the brain could be divided up into separate areas, each having its own restricted and unchangeable function. He based his opinion upon observations made to correlate the clinical symptoms manifested during the life of the patient with the organic lesions of the brain discovered after death. In 1870 Fritsch and Hitzig demonstrated by animal experiments that by the electrical stimulation of certain areas upon the cortex co-ordinated movements, in distinct groups of muscles, on the opposite side of the body, could be produced. These observations were important, but the work of supreme significance in cerebral localization was done by Ferrier, and published in 1873. Ferrier's researches were undertaken to test experimentally the conclusions reached upon clinical and pathological grounds by Hughlings Jackson. The result is known to all the world. Ferrier's investigations established firmly and finally the knowledge that there are points in the cortical matter of the brain definitely related to the motor and sensory functions of certain parts of the body. The way now was cleared for the surgeons, for Lister had afforded them safety, and Hughlings Jackson and Ferrier gave them guidance. The pioneer work in this direction was exclusively of British origin. One of the most dramatic occurrences in the whole history of surgery must surely have been the reading on August 9th, 1888, of a paper on the "Surgery of the brain and spinal cord" by W. Macewen of Glasgow. Cerebral surgery seemed to spring Minerva-like into the world, complete at every point. Macewen told of his first case in July, 1876; it occurred in a boy who developed an abscess in the immediate vicinity of Broca's lobe, as the result of an injury to the skull. Consent was not given to the operation urged by Macewen, notwithstanding the assumption by himself of the sole responsibility of advising and performing the operation; and the boy died. Macewen tells how "after death the friends acquiesced in the proposal to have the operation performed just as it would have been had permission to do so been granted during life. The skull was trephined, the brain exposed, and an instrument was introduced through the third frontal convolution for half an inch, when pus flowed through the incision, proving the accuracy of the diagnosis and giving poignancy to the regret that the operation had not been permitted during life. The abscess, about the size of a pigeon's egg, was situated in the white matter of the bases of the second and third frontal convolutions." In this case the precise spot in the brain which the abscess occupied was accurately determined from the localizing phenomena induced by the focal lesion.

Macewen's first successful cases—one of abscess and one of tumour of the frontal lobe—occurred in 1879. In the paper to which I have referred there were recorded 21 cerebral cases (exclusive of fracture of the skull with brain lesions), with 18 recoveries and 3 deaths. Of those who died all were in *extremis* when operated upon. At the time the paper was read 16 of the 18 were still alive;

one had died eight years after operation, and one forty-seven days after operation of tuberculous enteritis.

The record of the work achieved by this surgeon, working alone upon new problems and in a new field long before other minds had begun to stir, is one of the greatest triumphs in the history of scientific surgery. In the year 1884 Bennett and Godlee reported a case of cerebral tumour treated by operation, and in 1886 Victor Horsley reported three cases of cerebral surgery to the British Medical Association.

Great Britain may therefore make an undeniable claim to priority in respect both of the scientific work which made operation upon the brain possible and purposeful and of the procedures by which such operations were carried out with safety and accuracy. Germany here also has been a follower, not a founder. Her entrance into this field was of later date than that of the British, French, and Italian physicians and surgeons, but her work in it has been arduous and helpful.

The development of the surgery of the spinal cord was also dependent upon early experimental research. Galen, as is well known, had shown that there must be nerves of sensation and nerves of motion. Willis had made it certain that the nerves did convey sensation "and instincts to movements," but, as Sir Victor Horsley says, "no further determination as to the particular part of the nervous system which might be occupied in providing for such transmission of sensations and movements was made until 1811, when Sir Charles Bell, by his numerous investigations, was led to believe that separate parts of the brain and spinal cord subserved these two functions." Sir Charles Bell knew, of course, that the spinal nerve had two roots, anterior and posterior; he found by experiments that it was irritation of the anterior roots only that gave rise to the movements of the muscles. He says: "I now saw the meaning of the double connexion of the nerves with the spinal marrow." Bell's work was the first to prove that there was undoubtedly a principle of localization of function in the nervous system. When it had once been shown that this localization of function existed in the conducting nerve channels it was not difficult to see that the same difference must exist in those central parts to which, and from which, the nerves must pass. The surgery of the spinal canal was inaugurated by Sir Victor Horsley, who in 1887 was the first to open the spinal dura mater and to remove a tumour of the cord. In December, 1888, Bennett first divided the posterior nerve roots in a case of inveterate sciatica. In 1889 J. L. Faure performed the same operation for the relief of agonizing pain in a case of cancer of the uterus. Foerster's operation, the division of the posterior spinal nerve roots for the treatment of gastric crises and spastic paralysis, based largely upon the work of Sherrington and Head, dates from 1908.

CONCLUSION.

What, then, has been Germany's part in all the astounding progress of modern surgery? It has been the same in surgery as in every other science. Almost all fundamental discoveries in science, Dugald Clerk tells us, have originated in England, France, and Italy. In capacity for original thought the German mind is lacking. The brilliant and happy inspiration, the penetrating insight, the new vision are things for which we seek almost in vain in all German scientific literature. The fertile new thought giving a fructifying impulse to the work of others is rarely indeed of German origin. The German mind is of quite a different order. It is avaricious, industrious, methodical; it collects, if it does not accurately appraise, the work of others. It tabulates and registers and explains; it furnishes an intricate analysis, and illustrates by copious reference any subject with which it may deal. The new idea, originating almost always elsewhere, is given eager hospitality, is dissected and discussed at inordinate length; it may be put into practice with various alterations of technical procedure, and before long be claimed as a home product. For this act of intellectual dishonesty many of the German writers were not to blame; for a study of the literature of almost any subject in medicine chosen at random will show the amazing infrequency of any reference to the English or American literature, and very few indeed to the French. Thus in Riegel's work, the article on ulcer of the stomach has four and a half pages of references, seven references are to English writers, five are to papers by Riegel himself.

The name of Brinton is not even mentioned in this list, and yet it is probable that in his small book there is more of the truth of the matter of gastric diseases than in all the interminable treatises published by all the German physicians since his death. This almost exclusive reference by German writers to the works of their own countrymen was greatly helped by their publishers. In the last few years I have heard more than once from friends of my own in the medical profession in Italy, in Spain, and in Norway, that it was impossible to obtain from an English or American publisher a copy of any medical work on approval. A surgeon, desirous of seeing a new work in any special department of surgery, could only do so by purchasing the book outright and taking his chance as to the contents being to his liking. Any German publisher would send him all the books or journals he desired to see on approval. The copies of new German works on medicine were always sent to the editors of foreign journals for review. A new medical work in English was rarely, if ever, sent to Scandinavian countries, to Spain or to Italy, and to France or to Germany only in the case of a work of outstanding importance. To put this matter quite briefly, reference could always and quite easily be made by foreign physicians or surgeons to works published in Germany. It was difficult to hear of English works, and almost impossible to obtain them except by a speculative purchase. To the claims which Germany makes for intellectual supremacy we may therefore, speaking of scientific surgery, retort by a firm and flat denial. Not one single discovery of the first importance in the science or in the art of surgery can be placed to the credit of Germany. Nor, if we omit the Semitic element in the Germany of to-day, should we expect this to be the case. For the German mind is deductive; it is patient, laborious, massive; but it is not original. The German is not an innovator, but a renovator; not an explorer, but an exploiter; not a creator, but a collector.

A RECONSIDERATION OF THE PRINCIPLES AND METHODS OF HUGH OWEN THOMAS.*

II. SOME REFLECTIONS ON THOMAS'S SPLINTS AND PRACTICE.

By J. LYNN THOMAS, C.B., C.M.G., F.R.C.S.,

(TEMPORARY) LIEUTENANT-COLONEL R.A.M.C.; CONSULTING SURGEON AND DEPUTY INSPECTOR MILITARY ORTHOPAEDICS, WESTERN COMMAND.

I INDICATED in my first communication (July 15th, 1916) some of the many new resources which the genius of Hugh Owen Thomas devised for the improvement and advancement of a branch of surgery which since his time has failed to get its proper place in the sun owing to the birth, rapid growth, and brilliant youth of modern abdominal surgery. Nevertheless, Thomas's boots for the prevention and the correction of flat feet, Thomas's wrench for dealing with congenital and acquired deformities, such as club feet, neglected or unreduced Colles's fractures, and Thomas's "splints" for treatment of injuries, deformities, and diseases of the lower extremities very slowly but surely found a place in the records of the progress of orthopaedic surgery.

One of the factors which made Thomas's success in this department so unique was the personal attention he gave to every detail in the construction of the many devices or machines which he invented; it would have been impossible for him in his busy life in pre-telephone days to follow the orthodox but ineffectual fashion of resting dependent upon the services of a surgical instrument maker living at a distance from his consulting-rooms. He solved the problem by what appears to be a true inspiration—he had workshops built closely attached to his consulting-rooms. It was only by this means that he was enabled to carry out the enormous amount of experimental work entailed in working out the models of orthopaedic appliances; when he had perfected them he was able to recommend them with confidence to the profession. Orthopaedic surgery owes a lasting debt to Thomas for this bold if heretical act; for him it was the only way

* Continued from vol. ii, 1916, p. 72.

to reach a practical solution of daily perplexing orthopaedic problems. The majority of the Liverpool leechcraft of the eighteen-seventies treated him as a prophet is traditionally treated in his own country. However, it is pleasant to record that the names of Dr. A. F. Ayerton and Professor Rushton Parker are to be remembered as disciples in the local wilderness.

Although Hugh Owen Thomas's name is associated with some of his own orthopaedic inventions, nevertheless in justice to him it must be recorded that, as a historical fact, neither English nor American authors of books on surgery have down to the present time given him credit for evolving an epoch-making contribution of another kind to surgery. Not only have they omitted to do this, but they have committed the additional and extraordinary blunder of attributing it to a man who was a medical student when Thomas published his method! I refer to Thomas's method for the treatment of delayed union of fractures and disease of joints by what is known to-day as "Bier's method," but which was called by its originator "damming the circulation."

In a book published in 1886 by Thomas on the *Principles of the Treatment of Fractures and Dislocations*,¹ he wrote (pp. 29-30) as follows:

"During the early part of my practice I invariably interfered with the instances of delayed repair by either rasp, saw, wire, or pegging, operating upon an average of eight to ten cases annually, but during the last ten years I have better succeeded without direct interference although most of the cases submitted to treatment were less hopeful of success than any of my earlier cases. My change of opinion and practice commenced March, 1874."

In a footnote he adds:

"My view on the treatment of delayed union first appeared in the Liverpool and Manchester Surgical Report issued 1876."

It is worth while to give here an abstract of one of the many cases Thomas recorded in his book as evidence of the value of "damming." The story of one particular case and the drawings by which it is illustrated are in themselves enough to convince the most sceptical that the claim made for Thomas is well founded. This is the remarkable case of J. W. Jones, Wisconsin, U.S.A. The full story is given on pp. 46-47 of the book from which I have already quoted. The drawing with which Thomas illustrated the method is reproduced in Fig. 1, and his report of the case is as follows:

"Three years previously he was driving in a double horse wagon down a hillside road. The load proved more than the horse could control, and the wagon began to descend at a rapid pace, which so alarmed the driver that he attempted to leave the wagon, and while trying to do so fell and fractured the left humerus. He was attended to by a neighbouring practitioner, but the result of six months' treatment was failure of repair. From this defect several surgeons of repute in his own State tried to cure him, but they failed to remedy the fault and also declined resection. Consequently, he remained contented with the defective and useless arm, the condition of which much hampered his usefulness. In the early part of May, 1881, having ascended an elevation on his farmyard, the helpless condition of his arm caused him to overbalance himself and he fell down. This so annoyed him that he immediately left home, and arrived at my surgery sixteen days after the mishap. The forearm being placed at a right angle to the arm, as seen in Fig. 1, was slung by the wrist from his neck, and subjecting the points of fracture to mild percussion every four or five days, and the keeping up of a prolonged tumefaction for a distance around, above, and below the fracture, by means of india-rubber bands. No method of fixation was employed. This treatment was

watched daily for about three months, when the patient visited the Principality and spent some weeks with his friends, continuing the treatment; and on his return there was apparent progress towards consolidation, which gradually improved, so that after eight months of treatment repair was perfect and the patient returned home. He, in March 1882, reported his arm as now useful and gaining in muscular power."

In commenting upon the above, Thomas says, "This case, I think, may be accepted as testimony that we can, in the treatment of delayed repair, introduce a little more physiology with gain."

Any one who reads the first fifty-three pages of the book from which I have quoted would, I am sure, feel astonished that British surgeons should have allowed credit to be given to any other man than Thomas, and also would be surprised to find, considering how unsparingly he criticized American surgeons such as Sayre and Hamilton, that the same fiction has become established in the States. In the *History of Medicine*, by Garrison, Thomas's name is not even mentioned; but to Bier, who qualified two years after Thomas published his book, is given the

credit of introducing passive hyperaemia as an adjuvant in therapy (1903). In the same book Bier is also credited with introducing intraspinal anaesthesia with cocaine (1899), although in a later paragraph it is added that in this method he was preceded by Corning of New York City (1885). In dealing with this aspect of professional blindness of the old London school to advancements made in the provinces, I venture to quote Thomas's views from Part III of his *Contributions to Surgery and Medicine* (December, 1883):

"But the fact that the details of treatment, advised by me, have in a short space of time become so widely accepted . . . gives me presumptive evidence that my theories are correct, and will in time become generally accepted . . . indeed, in some instances my opinions have been adopted but in a manner I did not expect. For example, I have this day received a reprint of a lecture in which the whole of my teachings relative to diseased articulations have been adopted. The lecture is a skilfully condensed epitome of my writing upon the subject, and which I know the lecturer to be conversant with, and which are opposed to the views published by him

in the *Medical Record*, July 7th, 1883. To remove from the minds of his audience any suspicion of retailing second-hand information, the lecturer informs them: 'I have none of my fellow workers in view. We have all been followers of Dr. H. G. Davis.' This informed me that while the lecturer could ignore the source of the information he was circulating, yet he could lug forward a surgeon whose teaching has so injuriously influenced the practice of the surgery of diseased joints, and from whom he now joins me in dissenting. . . . Some six years back one of our Gallic neighbours published my views as his own, and they were thought so meritorious that a watchful foreign correspondent of an English medical journal gave us a reimportation. I could point out more examples of the 'by night' sort of compliment, but refrain lest my readers should suppose I believe that the most intelligent among us are also the most unscrupulous plagiarists."

Thomas's patience in resolving surgical and medical problems was of a rare type. I indicated in a previous communication that he had utilized an invention over a thousand times before recommending it to others. Thomas, dealing with problems of peace deformities, warned innovators to study and master his appliances before proceeding along a path in which he spent weary years of experimenting before perfecting and recommending them. And a further example may here be quoted as a warning to those who modify his inventions to refrain from so

FIG. 1.—Thomas's method of damming the circulation in a case of ununited fracture.

doing until they are sure that they have mastered the principles guiding the construction of his original surgical appliances. He relates that "the club-foot shoe, simple as it appears, was not adopted in a day; it is the outcome of thirty-two years' experience."

The tragedy of a summer scene (1916) of this war with over six battalions of disabled sailors and soldiers in their prime (30,000 to the end of May, 1916) is a thrilling logical reply to men who lack prevision and even now somewhat scornfully animadvert upon the new term, "military orthopaedics." Many of our soldiers who have been placed on the scrap-heap by medical boards are either curable or can be made more useful citizens; the permanent disabilities of a still larger number could have been prevented if the principles and practice advocated by Thomas had permeated our medical schools a generation ago.

The creation by the War Office of military orthopaedic centres, embodying Thomas's plan of establishing workshops in direct connexion with hospitals, is a development full of potentiality for good.

As an apt illustration of the value to me of new light from the Liverpool School of Orthopaedics, I would instance the treatment of ischaemic, or Volkmann's, paralysis. By appropriate treatment founded on Thomas's principles the patient's hand can be restored to full use and prevented from becoming a withered, shiny, atrophic, almost useless appendage. In connexion with this matter, I may quote from a letter received from Dr. A. A. Warden, Paris, dated March 2nd, 1916, as it reminds me of the occasion upon which I first gleaned information upon this subject. "It was a great disappointment to me," he writes, "not to see you and Robert Jones on your flying visit to Paris. I was reminded of you both the other day by a young Chasseur d'Afrique fresh from the trenches. Do you remember a good many years ago (1901) you and Jones were lunching with us and I got a small boy to show you a nasty fracture of the humerus involving the elbow-joint, with wrist-drop, trophic ulcers on his knuckles, palmar contracture, etc., and Jones told me about the hyper-extension of the wrist? Well, this was the boy; a strapping young fellow of 24, come back from cowboy life in America to serve his time..." My own advice had already been given to my friend according to the orthodox treatment of the day with the proviso that he should warn the parents as to the disappointing end-results of these cases. Since that time I have cured many such cases upon the lines he then indicated, and which have recently been published in the *BRITISH MEDICAL JOURNAL* by Colonel Sir Robert Jones, C.B., Inspector of Military Orthopaedics.

Such a fact encourages me to recall other methods initiated by Thomas which have proved exceedingly useful in the treatment of injuries, some of which under the treatment usually followed involve varying degrees of permanent disability. The war has made this matter doubly urgent. Modifications of Thomas's methods have to my knowledge been followed by results which, from an economic and wage-earning point of view, have been unsatisfactory, not to say disastrous. Most of the subject-matter to which I draw attention has already been referred to in the series of valuable articles recently contributed to the *BRITISH MEDICAL JOURNAL* by Robert Jones, but the particular items I would venture to add or to amplify have reference to:

1. Fracture of the femur.
2. Thomas's method of reducing simple backward dislocation of the ankle-joint.
3. Thomas's method of setting a Pott's fracture.
4. Thomas's method of reducing dislocation of the hip.
5. The after-treatment of amputations at or above the knee-joint.
6. Thomas's diagnostic method for detecting flexion deformities at the hip-joint.

1. Fracture of Femur.

Treatment of fracture of the femur in any situation except in the upper third is readily and efficiently carried out by following all the details of the method introduced by Thomas.

The time has come for an expression of opinion as to the safest and the best method of dealing with fractures of the femur. Every one who has had the opportunity of seeing

the complicated nature of such injuries in this war appreciates the difficulties with which the surgeon has to contend. After seeing some of the end-results one is nevertheless forced to state that there is no shadow of doubt that if those who were responsible for the treatment had appreciated the use of Thomas's methods, useful limbs would have been the result with normal gait in ordinary boots instead of an ungainly hobble in surgical boots with the assistance of sticks and crutches. I have seen many cases plated by different—not indifferent—surgeons in which the end-results have not been equal to those obtained by non-operative treatment by splinting.

From a fairly extensive personal experience of the use of screws, plates, and Lambotte's appliances, I have come to the conclusion that Thomas's method is better, safer, easier, and speedier. As in the case of open operations, however, the principles which govern the method must be carefully studied, and their application mastered in every detail, before the excellently good results achieved by Thomas can be obtained.

It is necessary to remember that Thomas maintained that extension alone could not be trusted to obtain proper alignment in a fractured femur. In his opinion it was also essential that the limb should have further support either at the back, the side, or front, or a combination of them according to circumstances. It was through these additional supports that proper forces were directed in order to keep the ends of the bone in correct alignment, consequently Thomas's knee-splint was made with lateral iron rods of sufficient strength to withstand the forces acting on the broken limb in three directions, namely, (1) longitudinal, (2) transverse, and (3) antero-posterior.

In order to appreciate how antero-posterior forces more especially act and counteract each other through the lateral bars of Thomas's knee splint, I have reproduced Figs. 2 and 3, with the explanatory letterpress from his book (Part VII).²

"Fig. 2 is a plan of the method of reduction. The fulcrum points are A E, the applied leverage force C D, and the fixed extension is shown at G, F being the adhesive gaiter with

Fig. 2.—Knee-joint flexion deformity; method of reduction.

cord attached to G, a sectional view of the lower end of a bed-splint, just as A is such a view of the lower supporting leather; E and B are also sectional views of the groin ring of a bed-splint, the B part having no duty to perform, as all leverage is gained by the resistance at A and E to the force C D; the dotted line is the supposed external rod of a bed-splint. C D are the reversible pads, which are the points of application of force."

"Fig. 3 shows reduction effected and the joint arrested by B from descending beyond strict extension. In both diagrams the direction of the travel of the arrow points

Fig. 3.—Knee-joint flexion deformity: reduction effected, the joint being arrested by B from descending beyond strict extension.

indicates the direction of force. In Fig. 2 the popliteal support B is absent; consequently the joint descends by the employment of force at the points C D, until the popliteal space comes in contact with the point of rest,

the cross mid-leather at B, the joint can have no rest, nor the sufferer ease from pain, the B support being the key to the position of 'greatest ease' and the reversible pads secure invariability."

Having effected the reduction of the deformity, the knee is fixed and the whole limb is in repose; the muscles, finding their conservative efforts needless, cease their action.

I have seen many tragic cases of preventable disabilities following treatment based on modifications of Thomas's practice.

It is not yet generally realized what an extraordinary amount of force is often required to overcome the shortening of a femur. It is also not yet universally realized that sagging deformities of fractures of femurs can be prevented by the application of antero-posterior forces acting upon the side bars of Thomas's splints according to methods he adopted.

In the whole range of unsatisfactory end-results of treatment of fractures I know of none so lamentable as those of the femur.

Shortening of a lower limb from one to five inches, accompanied by sagging deformities, are grievous calamities; they can almost invariably be prevented, or can often be remedied at a later stage by the application of powerful forces applied through pulleys. Thomas's knee splint made according to his instructions is infinitely the best means of dealing with such cases; its side bars are strong enough to stand a force exceeding that of the weight of the patient in the longitudinal stress; they are strong enough also to withstand the transverse and antero-posterior forces necessary to maintain the limb in the line which ensures absence of sagging or latero-angular deformities. The want of appreciation of the part played by the side-bars is a contributory factor to failure in treatment.

The aluminium splinting which has been used by some surgeons in the treatment of fractured femurs is too weak and pliable to withstand the requisite forces, and it must be condemned as a trap for the unwary in treating the type of cases I allude to; it is easy to demonstrate the relative strength of aluminium splints for the thigh and Thomas's. Once a lateral bar of the aluminium splint is bent its resistance to a powerful longitudinal force is gone—it has no resiliency, an essential point in the maintenance of efficiency—whilst it is never strong enough to withstand the transverse forces which have frequently to be applied to the lateral bars of a Thomas's splint. Any one can satisfy himself of the truth of what I state, and measure the strain by applying the forces mentioned to either type of splint appropriately fixed to a spring balance; a more homely demonstration is obtained by trying to bend both across the knee in order to test the give of the metals to transverse strain; the longitudinal strength of an aluminium or iron splint can easily be tested by pushing against the ring when the foot-end is placed in the corner of a wall. Thomas's knee-splint gives confidence and safety; aluminium splinting neither.

Even Thomas, with his perfected knee-splint, regretfully records that "in the upper third of the femur on several occasions, during an experience extending over thirty-two years, it has been my lot to fail in 'restoring' several fractures of the femur close to the trochanter." It is interesting to observe that this special difficulty which baffled Thomas's ingenuity has since been overcome by the introduction by Robert Jones of the "abduction frame" by which proper alignment of the broken bone can be maintained and the normal length restored.

2. Fractures about the Ankle.

Thomas's method for the reduction of simple backward dislocation of the ankle-joint is shown in Fig. 4. Thomas states that "where delayed extension to two or three weeks in the reduction of the backward dislocation of the ankle-joint, or in cases where no skilled assistance is at hand, the illustration shows how the surgeon can much

increase his individual powers, and succeed without the aid of an assistant or of an anaesthetic. From the illustration it will be seen that the power of the surgeon's arms is assisted by the efforts of his trunk muscles, through the medium of a bandage passing behind his neck and under the patient's heel; a counter force is gained by attaching the patient's leg to the surgeon's foot with a bandage. The surgeon, as he finds best, may employ both hands to the patient's heel, or, as in the illustration, one hand to the heel and the other to the leg."

FIG. 4.—Method for the reduction of simple backward dislocation of the ankle-joint.

3. Setting a Pott's Fracture.

Thomas's method of reduction of a Pott's fracture is illustrated in Figs. 5 and 6. Fig. 5 shows the fracture with the common valgus deformity. Fig. 6 shows how Thomas reduced such a deformity six or seven weeks after date of injury. He states "that the reader will notice that the manner of employing the necessary force and counter

FIG. 5.—Pott's fracture, showing common valgus deformity. a, Inside of leg. b, Outer aspect of foot and heel. The lettering in Fig. 6 corresponds.

FIG. 6.—Thomas's method of reduction. a, Site of counter force. b, Site of opposing force.

force, is similar to that for the reduction of an ancient dislocation of the ankle, but with this difference, the counter force attached to the surgeon's foot acts upon the inner aspect of the patient's leg, while the opposing force, the towel over the surgeon's neck, is applied to the outer aspect of the patient's foot and heel, being further supplemented by the surgeon's hands applied to the same locality."

4. Method of Reducing Dislocation of the Hip.

Thomas states, "My general method of reduction is shown in sketch by Fig. [7]. By a glance at that figure, the reader will perceive that the pelvis is fixed to the ground by a looped towel, passing over the patient's groin and under the arch of the operator's foot, while the flexed knee of the patient is drawn over the operator's thigh, who, grasping the patient's leg, flexes the knee more, also using the leg as a lever to strain the fixed point, the groin towel. By this arrangement the operator is personally able to apply an amount of force approaching that to be gained by the use of the 'tripod,' which is probably seldom

procurable. By this plan the operator is free, though aided by extra force, to perform his flexion, rotation, abduction,

FIG. 7.—Method of reducing dislocation of the hip (Thomas).

and sudden extension without interruption. It may happen that the patient to be operated upon may be a very tall man and the operator a short person; the disparity between their respective limbs would much lessen the leverage—extending power of the operator. This hitch can be easily arranged; the operator should pack the upper surface of his thigh, the fulcrum point; this act practically lengthens his leg for the purpose intended."

5. Thomas's Frame for Treatment of Amputations at or above the Knee-joint.

Fig. 8 shows a frame Thomas² found to be "labour saving" in the after-treatment of amputations at or above the knee-joint. I have introduced this frame into several military hospitals, and it has given every satisfaction; it is constructed of five-sixteenths inch iron wire, and its mode of application is shown in Fig. 9. The wings of the frame can be altered to fit different limbs, and the angle of fixation can also be altered. The wide lower wings cover a large area of soft bed and do not sink into it, and on them a weight can be fixed to anchor and to steady the frame.

FIG. 8.—Frame for supporting thigh stump.

FIG. 9.—The same applied.

6. Thomas's Method of Detecting Flexion Deformities at the Hip-joint.

I think it desirable to reproduce a diagram (Fig. 10) illustrating the method Thomas introduced over forty years ago for detecting flexion deformities. My reason for doing so is that I have seen a large number of thigh amputations on the Continent with artificial limbs fitted on to the deformed stumps. In this country a large number of stumps with similar troubles are sent by well-known surgeons to be fitted for artificial limbs. There is one factor in determining flexion deformities at the hip which is not perhaps fully recognized. I refer to the posture of the amputated limb in bed; it is almost invariably propped up on pillows during convalescence. Some of the most difficult deformities to correct occur in amputations in the upper third of the thigh. Dr. Mennell very kindly showed me a most ingenious and simple appliance which he has introduced at the Military Orthopaedic Hospital, Shepherd's Bush, for correcting this deformity,

but it is important to prevent the occurrence of this deformity, and Thomas's frame is valuable in attaining this end.

In conclusion I desire to emphasize a fact which is not yet generally realized by the profession, that the amount of force used by Thomas and Robert Jones in the treatment of orthopaedic cases is enormous—far greater than that in general use. For example, the force of the pull reducing dislocations of the ankle or of a Pott's deformity after the method referred to in this paper easily exceeds 300 lb. weight. In wrenching a foot a Thomas's wrench 12 in. long and applied in the way that Robert Jones uses against his hip, I have without much strain raised a dead weight of over a quarter of a ton (564 lb.).

The strength of the side bars of Thomas's knee splints even for children is at least four times as strong as the aluminium splint which is used for adults, whilst Thomas's adult splint will stand more than ten times the force which renders the aluminium rods perfectly useless.

FIG. 10.—Thomas's method of ascertaining the amount of flexion deformity at the hip. The forearm of the sound side is used as a means of fixing the sound lower limb to the trunk during examination of the diseased side, in order to correct the compensating kyphosis.

CONCLUSIONS.

By setting a fractured limb Thomas meant that the limb was to be restored to perfect symmetry, that is, proper alignment and length.

In order to do this he employed forces which ran into hundreds of pounds at the time of the setting, by means of pulleys, levers and special appliances constructed for the purpose. This mechanical treatment is founded upon principles which Thomas published in 1875.

I desire to express my gratitude to my friend Colonel Sir Robert Jones for valuable gifts of books published by Thomas, and I am also grateful for having had so many opportunities of seeing his work, which convinced me that the vogue of operations for plating fractures and for tenotomy is only a passing fashion and will, as soon as the Liverpool School of Orthopaedics is fully appreciated, die a natural death.

THE annual meeting of the British Dental Association was held on July 28th, in the hall of the Medical Society of London, under the chairmanship of Mr. Norman G. Bennett. The annual report showed that the present membership of the association is 2,600, of whom 600 are serving with the forces, either as dental surgeons, or as combatants. Mr. W. H. Dolamore was re-elected President of the Association, and in his address referred to the excellent work performed by the Canadian Army Dental Corps, which encouraged him to suggest the advisability of instituting an army dental corps for the British army.

THE ORIGIN OF ORTHOPAEDIC SURGERY.

BY

A. ROCYN JONES, M.B., B.S., M.R.C.S.,

SURGICAL REGISTRAR, THE ROYAL NATIONAL ORTHOPAEDIC HOSPITAL,
LONDON.

THERE WAS a work, in two volumes, entitled, "*Orthopaedia; or, The Art of Correcting and Preventing Deformities in Children*," translated from the French of M. Andry, Professor of Medicine in the Royal College, and Senior Dean of the Faculty of Physick at Paris." It was printed by A. Millar at Buchanan's Head in London in 1743. M. Andry explains his choice of the term as follows:

As it is not within the reach of every Reader to understand the Title of Orthopaedia, which is affixed to this Book, I shall begin with explaining it: after which I shall give an Account of the Book itself. But in the first place I must take notice of two Pieces which have been published upon a subject akin to this, though they differ a good deal from it; the first in the year 1584, by Scèvele de Saint-Marthe, and the second in the year 1656 by Claude Quillet. As to the Title, I have formed it of two Greek Words—namely, *ὀρθος*, which signifies straight, free from Deformity, and *παῖδιον*, a child. Out of these two Words I have compounded that of Orthopaedia, to express in one Term the Design I propose, which is to teach the different Methods of preventing and correcting the Deformities of Children.

The expression seemed to me the more allowable, that the two celebrated Authors above cited, have made use of Terms of the same kind: the first in giving the Title of *Paedotrophia* to a Treatise upon the Manner of suckling Infants; and the second that of *Callipaedia*, to a Poem upon the Method of getting beautiful Children: both which Titles are likewise taken from the Greek: the first from *παις*, an Infant, and *τροφή*, Nourishment; and the second from *καλός*, beautiful, and *παῖδιον*, a Child.

In a supplement at the end of the second volume mention is made of a series of critical articles, published weekly, by the Abbé Desfontaines, under the title of "Observations upon Modern Writings," and Andry says that, "In this particular one of October 14th, 1741, he (Desfontaines) confines himself to my *Orthopaedia*." The term "orthopaedia" was, therefore, probably used for the first time in 1741, a view corroborated by William Adams, who states that Andry published his book in Paris in that year.

Hippocrates used bandages for the cure of varus, and the only advance on this method, for centuries, was the employment of mechanical appliances. Orthopaedic surgery can only be said to have really begun with the introduction of tenotomy. The first record of tendon cutting was that performed by Lorenz, on the advice of Thilenius, in 1784. He cut the tendo Achillis through an open wound for talipes equino-varus. The first account of subcutaneous tenotomy is by Petit in 1799, who cut the tendo Achillis for a retraction of the heel after Chopart's operation. In 1816 Delpech, of Montpellier, conceived the idea of treating talipes equinus by cutting the tendo Achillis subcutaneously after first transfixing the leg just in front of the tendon. Owing to a mishap in his first case he did not pursue the operation, although in his work, *De l'Orthomorphie* (Paris, 1829) he lays down very sound rules for the operation and subsequent treatment. Stromeyer, who greatly benefited by Delpech's rules, divided the tendo Achillis by subcutaneous puncture in 1831, and by a series of successful cases established the division of tendons on a secure basis, and ensured its reception as a standard operation in surgery.

Stromeyer published his results in his book on operative orthopaedic surgery (Hanover, 1838). A young English physician in London, W. J. Little, who had talipes equino-varus following infantile paralysis in early childhood, had consulted Sir Astley Cooper and most of the approved surgical authorities in London, but from none did he receive the slightest prospect of cure. In June, 1836, he went to Hanover, and his tendo Achillis was divided by Stromeyer, who later afforded Little the opportunity of practising the operation himself. Going afterwards to Berlin, he taught the operation to Dieffenbach, and treated upwards of thirty patients in that city; Little was therefore the first to introduce subcutaneous surgery into the Prussian capital. Through Johannes Müller's kindness he was also allowed to dissect numerous deformed fetuses contained in the Berlin Museum. In Stromeyer's own words, Little became "the apostle of subcutaneous surgery," for until the conversion of Dieffenbach the German universities regarded the operation with dis-

favour, although afterwards Stromeyer himself was elected professor of surgery at Erlangen.

On his return home Little at once introduced the operation, performing his first tenotomy in London on February 20th, 1837, and a few weeks later attended a discussion at the Royal Medical and Chirurgical Society on this new surgical procedure. The following year he was instrumental in founding the Royal Orthopaedic Hospital, the first public meeting of which was held in 1840 with the Earl of Eldon in the chair. This was the beginning of orthopaedic surgery in this country. In 1839 Little, who was now assistant physician and lecturer on comparative anatomy at the London Hospital, published the first English book on this branch of surgery, *A Treatise on the Nature of Club Foot and Analogous Distortions*, and dedicated it to Sir Astley Cooper, who had displayed a warm interest in what Little had been able to demonstrate. Little continued to write much, and in 1853 published another important work, *On the Nature and Treatment of the Deformities of the Human Frame*. His description of spastic diplegia in infants reveals his power as a clinician, this affection being often referred to as Little's disease.

Of the many workers who have appeared in this field since Little, two stand out prominently—William Adams and Hugh Owen Thomas. William Adams followed closely in Little's steps, and did as much as pre-antiseptic days would permit to advance the subject. He joined the Royal Orthopaedic Hospital as assistant surgeon in 1851, and did much good pathological work. His book, *Club Foot: its Causes, Pathology, and Treatment*, based on his Jacksonian Prize Essay of 1864, was published in 1866. He devised operations for ankylosis at the hip-joint, and for Dupuytren's contraction, and introduced several ingenious corrective appliances. Among other works published by him was one on *The Reparative Process in Human Tendons*, based on post-mortem examinations and experiments on rabbits. John Hunter and Paget had previously studied tendon repair in animals, the former, it will be remembered, being induced to do so through rupturing his tendo Achillis when dancing.

Hugh Owen Thomas of Liverpool was practically a contemporary of Adams. He was a man of extraordinary originality of view. In 1869 he published a well-illustrated monograph on *A New Method in Applying the Wire Ligature in Compound Fractures of the Lower Jaw*, in which he anticipated much of the present day method of dealing with this lesion. His now famous hip and knee splints were figured for the first time in *Diseases of the Hip, Knee, and Ankle* (1875). In this book Thomas adopted the great principle of mechanical and physiological rest, in the treatment of surgical diseases, laid down by John Hilton in his famous lectures at the Royal College of Surgeons, 1860-1862. Hilton very successfully applied his principle to diseases of the hip-joint by means of a splint, which consisted of a leather case from the pelvis to below the knee, with a posterior steel extension and foot-piece to fix the rest of the limb. The Thomas splint was an improvement on this, in that it was simpler and could be variously modified for correction purposes in cases with flexion.

It took many years, however, for Hilton and Thomas to change surgical opinion upon the treatment of joint tuberculosis. Thomas was the first to point out the cardinal principle of relaxing paralysed muscles, and thus preventing over-stretching; he carried it out in practice with his metal splint for dorsiflexion at the wrist, and with his caliper for maintaining extension at the knee.

THE USE AND ABUSE OF BONE GRAFTS.

BY

T. P. McMURRAY, M.B., B.Ch., CAPTAIN R.A.M.C.(T.),

SURGEON, NORTHERN HOSPITAL AND INFIRMARY FOR CHILDREN,
LIVERPOOL; MILITARY ORTHOPAEDIC BASE HOSPITAL,
ALDER HAY, LIVERPOOL.

THE operation of bone grafting for non-union of fractures is by no means a new one, and it is one which has undergone many alterations since its inception.

The first bone-grafting operation was done in 1809, when Mercet obtained successful healing of bone plates in the skull after a trephine operation.

A great number of substances, such as solidified milk,

have at various times been suggested which should replace bone tissue and act as a scaffolding for the formation of new bone, but all of them have fallen into disrepute, as the great majority were either quietly discharged as foreign bodies or else led to sepsis being started or restarted.

In 1881 Macewen wrote a paper explaining his method of bone grafting in a case of ununited fracture. In this case he used wedges of bone removed from rachitic tibiae broken up into very fine pieces and placed between the freshly chiselled ends of the broken bone; thus new bone was formed.

The modern technique follows that of Albee, and aims at obtaining a long solid unbroken graft consisting of periosteum, compact bone, and marrow which will unite on each side with the two fractured ends, and which will increase in size until it is as large as the receiving bone.

The causes of non-union are many and varied, and unfortunately some or all are present in a large majority of the cases of fracture now reaching the military hospitals.

The first and in all probability the most common cause of non-union is want of fixation of the fracture. This is usually due to the fact that the splints are so placed that they control the region of the fracture alone, and do not extend so as to control the joints on either side. Without this there can be no proper fixation.

The second cause is the presence of foreign bodies, either metal or cloth, or pieces of tissue such as muscle or fascia between the fractured ends, or the occurrence of virulent suppuration, which inevitably causes a localized sclerosing osteomyelitis, and so shuts off the medullary cavity with its powerful osteogenetic function.

The third local cause of non-union is loss of bone tissue, either due to the destruction and loss of bone tissue caused by the missile, or else to the removal by operation of apparently loose pieces of bone which, if left *in situ*, would in the large majority of cases unite firmly in position, and so form a sound thickened bone.

Delayed Union and Non-union.

The first question in regard to fractures which have not united is to distinguish between delayed union and non-union. A large number of cases are met with in which, for some cause other than the interposition of tissue between the fractured ends, there is delay in the union of a fracture. The cause may be local, such as we have just mentioned, or it may be some general debilitating process, and if this is treated and cured the fracture will unite readily. Apart from these, however, there are a number of cases in which no local or general cause can be found for the want of union. It would almost seem as if there was a definite idiosyncrasy on the part of the patient, or, indeed, on the part of the particular bone, so that one fracture may not unite, whilst another in the same patient at the same time may unite firmly and rapidly.

There is no time limit beyond which it can definitely be said that a fracture which has not united has passed the stage of delayed union and is in a state of non-union. That a fracture is ununited can only be said when it has undergone proper treatment by fixation, venous congestion, and the administration of thyroid extract for a period of at least three months without the occurrence of union at the site of fracture.

If non-union of a fracture has definitely occurred one must then decide, "How long should the interval be between the cessation of all discharge and the time of operation?"

It has been found by experience that if the intervening period is less than six months many of the cases operated on will become septic even when the wound has remained soundly healed without any signs of infection for some time before the operation, and where the strictest asepsis has been carried out at the operation.

This recurrence of sepsis has been attributed to a change in the condition of the blood, which, instead of being, as it normally is, a germicide, becomes instead a culture medium for bacteria, but the most probable explanation is that in shell or bullet wounds, especially in those which have produced a fracture, a large amount of fibrous tissue is formed owing to the extensive wounding and opening up of the neighbouring tissues and the spreading of the sepsis along the fascial planes.

As healing takes place small localized patches of sepsis are found which are completely surrounded by their fibrous

tissue wall, and are thus to all intents and purposes completely shut off from the blood and lymph stream; these foci are opened up during the course of the operation, and lead to a recurrence of the sepsis. This I have found to be the case in several patients in whom small pieces of metal were present apparently perfectly aseptic; when cut down upon they were found to be localized in a fibrous capsule, in which they lay bathed in pus.

In one case on which I operated recently, intending to do transplantation of bone, a small abscess was found in the centre of one of the broken ends; it was only after opening into the shaft of the bone that the abscess with its central sequestrum was seen. This case had remained soundly healed without any discharge and with no sign of redness or inflammation for a period of four months.

The fixing of the interval at six months is due to the fact that in the eighteen cases of bone grafting which I have done and in which this interval had been left there has been no instance of a recurrence, but in the first cases operated on without this interval there were two cases of recurrence of sepsis.

The operation of bone grafting should, then, be performed after the proper interval has elapsed since the cessation of all discharge. There are certain principles about the graft which should be rigidly adhered to.

1. The Graft should be Autogenous.

In one case which came under my care a piece of rabbit's bone was transplanted into an ununited ulna. There can, however, be no advantage from these exogenous grafts; they complicate the operation to a very marked degree, and lead to great increase in the risk of sepsis at the time of operation.

In this particular case there was no possibility of success owing to the fact that the operation was performed and the exogenous graft implanted whilst the wound was still actively discharging, and that the bone transplanted had an outer covering of compact bone on all sides which left no possibility of expansion of the transplant to the size of the receiving bone; lastly, the transplant had been fixed in position by means of wires which caused marked loss of bone tissue.

2. Situation from which Graft is Removed.

The graft may be removed from one of two positions: (a) Either from the subcutaneous surface of the tibia, which on account of its extent and its accessibility is the site usually preferred, or (b) from the upper or lower ununited fragment, by what is known as the sliding graft.

In all cases in which the patient has no objection to what may be called the double operation the graft should be taken from the tibia. This is not because the grafts may be removed from the tibia much more easily and of much larger size than from any other bone, but also because in the case of every ununited fracture there is a condition of osteo-sclerosis at the ends of both the fragments, which is greatly increased in the case of an actively suppurating compound fracture such as a gunshot fracture. If sections of the ends of the fragments are made the medullary cavity will be found to be lost for a space of half an inch or an inch on either side of the fracture, and the density of the bone is greatly increased, so that it here becomes very much harder than normal, and frequently it is almost impossible to use an ordinary chisel. Thus any bone graft removed in this region will have to extend so as to pass beyond these thickened portions and reach the healthy bone on either fragment.

3. The Graft should Consist of Periosteum, Compact Bone and Marrow.

In several cases in which the graft has been used without periosteum, the graft has united firmly, showing that this membrane is not essential. Periosteum stripped from the bone in its course, but attached at the two ends, can throw down a layer of new bone on its inner surface, so that the structure raised from the surface of a bone by means of an elevator, whether it is periosteum alone or periosteum and attached bone cell, can undoubtedly form bone.

Union of a bone graft consisting of compact bone and medulla can undoubtedly occur, and has done so on many occasions, thus showing that the periosteum has at best

only a subsidiary part in bone formation, but a graft consisting of compact bone and periosteum alone will in the large majority of cases not unite, thus proving the great importance of marrow.

One case of non-union of the radius which I had under my care illustrated this point. A graft of bone had been taken from the subcutaneous border of the tibia consisting of compact bone and periosteum alone without marrow. This graft remained in position in the arm for three months without any sign of union, and was then quietly discharged through the skin.

4. Size of Graft.

The graft should be at least two inches longer than the space between the fractured ends which it is going to fill. The older method of bone transplanting or grafting as used by Macewen aimed at freshening up the fractured ununited ends of the bone and filling up the space between them with the chopped up pieces of bone which naturally consisted chiefly of compact bone, and which lay in contact with each other and with the freshened bone ends. But the chief power of union in a bone graft comes from the presence of the bone marrow and the adjacent more porous bone which is completely absent from the fractured ends for a distance of half an inch to an inch, owing to the obliteration of the medullary cavity; therefore the transplanted bone fragments came into contact only with the sclerosed ends of the bone in which the blood supply is markedly diminished, and the osteogenetic power almost absent. Any bone graft which is taken should be long enough to extend beyond this sclerosed area on both fragments.

5. Preparation of Graft.

The graft may be obtained from the tibia or from the fractured bone itself at a higher level in two ways.

(a) By means of a circular saw, with either one or two parallel blades, driven either by a small motor or by hand by means of a large wheel turned by an assistant at some distance from the table. With this the bone is sawn down to the medulla for the required distance, and then transferred to the site of the operation.

(b) The other method is by means of chisels and a bone drill. If an attempt is made to remove a bone graft by means of a chisel alone it will be found that the bone becomes splintered and almost useless for the purpose in view. If, however, the bone is first drilled down to the medulla along the line of the proposed bone graft, then the subsequent use of the chisel is without danger, as the bone breaks between the drill holes.

When the graft of sufficient length has been obtained a bed should be made for its reception in the two fragments at the site of fracture by removing from these broken ends a wedge of bone equal in breadth to the graft and so placed that the graft lies on either fragment for a distance of at least $1\frac{1}{2}$ in. When the graft has been placed in the bed prepared for it it should be anchored there by means of catgut or small bone pegs. No metal, such as plates or wires, should ever be used in its fixation, owing to the fact that metal of any description placed in a bone acts as a foreign body and leads to atrophy of the bone round the site of the metal, thus hindering bone formation which would otherwise occur between the fragments.

It has been shown that in a plated fracture bone is thrown out on all sides except at the site of the plate or screws. There is atrophy of bone which can frequently be seen in the x-ray photograph as a light area round each of the screws.

The osteogenetic action of the bone graft should not be opposed by the inhibitory action of the screws. As regards the after-treatment the newly implanted bone graft should be kept in position without any stress or strain for a period of at least two months.

Many forms of splints may be used for this purpose, but the most efficient method of fixation is to apply a plaster-of-Paris case to the whole limb, so that all the joints which by their movements could in any way act on the transplant are completely fixed. This case should be put on immediately after the operation. It is not at all necessary to leave its application over until the stitches are taken out, as they can be easily removed through an opening made in the plaster directly over them. This is a marked advantage, as the surgeon has in his mind at the

time the exact position of the limb in which the graft lies most snugly in its bed.

When the plaster has been removed after two or three months the transplant will probably be found to be firmly united, but in case the union is not firm the limb should be immediately replaced in plaster or splints and treated by fixation and venous congestion, with the administration of thyroid extract, which undoubtedly tends to promote the deposit of callus and so to hasten the union.

The failures of bone-grafting operations which I have seen have been due to (1) want of proper interval since the cessation of discharge, (2) insufficient length of the graft, (3) inefficient fixation, (4) the use of the sliding graft.

A POSSIBLE ELECTRO-CARDIOGRAPHIC SIGN OF MYOCARDIAL CHANGE.

BY

S. RUSSELL WELLS, M.D., B.Sc., M.R.C.P.,

PHYSICIAN TO THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART,
AND PHYSICIAN TO THE SEAMEN'S HOSPITAL, GREENWICH;

AND

J. STRICKLAND GOODALL, M.B., M.R.C.P.,

F.R.C.S., F.R.S. EDIN.,

ASSISTANT PHYSICIAN TO THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART, AND LECTURER ON PHYSIOLOGY AT MIDDLESEX HOSPITAL.

DURING the last few years the attention of those interested in diseases of the heart has been increasingly directed towards the signs and symptoms by which impairment of the myocardium can be diagnosed. The importance of the heart muscle in the prognosis of cardiac disease is no new discovery; the pioneers of cardiology fully realized that grave valvular lesions could be compensated for by efficient heart muscle, but while their methods of examination permitted surprisingly accurate diagnosis of valvular defects, there was by no means the same precision in their means for determining the state of the heart muscle.

Though modern methods of investigation have somewhat increased our knowledge in this direction, it is not possible, as yet, to say that we can as accurately visualize in any individual case the condition of the myocardium as we can, for instance, that of the aortic valves. Any method of investigation, therefore, which tends to throw light on this problem is worthy of serious consideration.

Numerous attempts have been made to arrive at a just estimate of the condition of the myocardium in regularly acting hearts, such as the careful consideration of the subjective symptoms, the response of the heart to exercise, the relative intensity of the first apical and the aortic second sounds, the length of the A.V. or P.R. interval, and the inversion of the second ventricular or T wave of the electro-cardiogram in at least two of the usually employed leads. No doubt all of these methods have their uses.

We have had during the last few years the opportunity of examining several thousand cardiac cases and of comparing the clinical findings, and in a large proportion the subsequent histories as well, with the electro-cardiograms. As a result of these observations we have become increasingly convinced that the height of the second ventricular or T wave affords some indication of the efficiency with which the ventricles are functioning.

The second ventricular wave marks the end of systole, and it is generally agreed that it is produced by some portion of the base remaining in a state of contraction after the contraction of the apex has ceased. There is not, however, the same agreement as to the exact site of this residual contraction. Sherrington considers it to be the aortic base; other observers are not disposed to localize it so definitely. From the point of view under discussion this is immaterial; the essential question is whether very low or absent T waves in an electro-cardiogram indicate myocardial impairment or not.

With a view to bringing our opinion in some measure to the proof, it seemed to us that if we could get cases in which there was clinical evidence of myocardial change, and in which the electro-cardiogram showed small or absent second ventricular waves, and if on treatment these waves increased or reappeared in electro-cardiograms concurrently with an improvement in the clinical condition, it would, to a certain extent, support our contention.

Unfortunately, marked myocardial degeneration is not a condition which, as a rule, easily or rapidly yields to treatment, so that suitable cases for such an observation are by no means common. It seemed to us, however, that cases of syphilitic myocarditis might afford the required material, and we now think two such cases may be worthy of being put on record.

CASE I.

Mr. W. X., aged 45, was seen in consultation with Mr. Allport by one of the writers (J. S. G.) in June, 1915. He contracted syphilis in 1901; the symptoms were severe, ulceration of the tongue being practically continuous until 1905, when he

FIG. 1.

went to Aix and had mercurial inunctions; the tongue healed. In 1912 he complained of pain in the chest, flatulence, and occasional vomiting; his Wassermann reaction was strongly positive. Salvarsan and mercurial injections were given; his condition, however, got worse, and he suffered from pain radiating down the right arm and a systolic murmur was audible at the apex. A series of neo-salvarsan injections was given, which was followed by a long course of mercury and iodides; the murmur disappeared after the first injection. In 1914 he had a very bad attack of typhoid fever, being laid up from January to April; the tongue again became ulcerated, but cleared up under iodides. He nearly died of heart failure.

In June he underwent another course of inunctions at Aix. An x-ray examination of the heart showed slight enlargement,

FIG. 2.

both to the right and to the left, no aneurysm, but enlarged glands in the mediastinum; the finger nails were corrugated.

When seen in consultation in June, 1915, he complained of pain in the left side, only being able to sleep when lying on the right side, pain over the sternum, slight dyspnoea, and a sensation of sickness over his heart on exertion, which was increased by exercise and after meals; there was no cough nor oedema. The area of cardiac dullness was lightly enlarged, the apex beat being in the fifth space near the nipple line; the first sounds were weak but no murmur was audible; the pulse-rate 100, blood pressure 140, he did 10,107 foot-pounds of work in two minutes, there was a poor reaction to work and he showed signs of collapse.

The electro-cardiogram (Fig. 1) showed an absence of second ventricular or T waves in leads 1 and 2 with inversion in lead 3.

He was treated by mercurial inunctions and steadily improved. When examined again in 1916 his pains had disappeared, the cardiac dullness was still slightly increased, but the apex beat was well within the nipple line, the first sound at the apex was flapping and short, the second reduplicated, the aortic and pulmonary second sounds were audible, the blood pressure was 118, the electro-cardiogram (Fig. 2) showed well marked second ventricular waves in leads 1 and 2 with inversion in lead 3. It will be observed that figures 1 and 2 show the sign attributed to left-sided preponderance.

CASE II.

Mr. Y. Z., aged 30, was seen July, 1916, in consultation with Dr. Green, of Finchley, by one of the writers (S. R. W.); he had had scarlet fever when 13 and contracted syphilis in 1903; he was treated for two years. Beyond occasional sore throats he had

FIG. 3.

suffered from no other illness. He complained of dyspnoea and palpitation on exertion and a constant feeling of lassitude, and said that he fainted on excitement or any over-exertion. He was markedly anaemic, the pulse-rate was 60, volume very small, the apex beat was diffuse and almost impalpable, the area of cardiac dullness was greatly enlarged, extending from 2 in. to the right of the mid-sternal line to over 5 in. to the left; x-ray examination revealed a very large heart, the shadow agreeing with the limit as defined by percussion; it was obviously soft and atonic as it was horizontally placed and seemed to be lying on the diaphragm. The first sound at the apex was very faint and flapping in character, the second sounds were audible at base and apex, no murmurs could be heard; he was not exercised nor was his blood pressure taken as he fainted twice during examination; the urine had a specific gravity of 1024 and contained no albumin. On account of the patient's nervous condition and the ease with which severe

FIG. 4.

fainting attacks were provoked the blood was not taken for the Wassermann reaction. His electro-cardiogram (Fig. 3) showed very poorly marked second ventricular waves in lead 1, almost absent in lead 2 and completely so in lead 3.

He was treated by Dr. Green with mercurial inunctions, and examined again in consultation in September, 1916, when his general condition was distinctly improved; the cardiac area now measured 1½ in. to the right of the mid-sternal line and 4½ in. to the left; this was confirmed by x-ray examination. The electro-cardiogram (Fig. 4) showed definite T waves in the first and second leads, and indications of them in the third. Antisyphilitic treatment was continued, mercury and iodides being given. He was seen again in March, 1917, when there was a marked improvement. The cardiac dullness was now 1½ in. to the right of the sternal line and 3½ in. to the left;

this was confirmed by x-ray examination. The shadow of the heart, besides being smaller, was of much more normal outline. The electro-cardiogram (Fig. 5) showed well-marked T waves

FIG. 5.

in leads 1 and 2 and distinct T waves in lead 3. Unfortunately he moved somewhat when lead 2 was being taken, so the record was not as neat as could be wished.

While it is not contended that these two cases in themselves are conclusive proof that absence of the second ventricular waves in the electro-cardiogram indicate myocardial change, they are certainly suggestive, and tend to confirm many other curves in our possession. It is to be hoped that other observers will put on record their experiences, not only in syphilitic cases but also in other forms of myocardial involvement, since it is only by numerous observations, and above all by electro-cardiographic observations, carefully correlated with the clinical findings at various stages in the history of the same patient over prolonged periods, that anything like certitude can be reached.

MEDICAL, SURGICAL, OBSTETRICAL.

TONSILLECTOMY.

As I pointed out in a paper read at the International Congress in 1913, surgeons are prone to debate the merits of this or that technique for tonsillectomy simply from the standpoint of the removal of the tonsil. Some of the remote after-results, elicited by examining a large number of patients from one to eight years later, are of the greatest practical relevance. As regards technique, each man should, of course, use the method and instruments with which he gets the best results. Considered broadly and without detail, operators range themselves into three groups: (1) Those who use nothing but some form of guillotine, claiming that by this method every tonsil is removable in its entirety, capsulated; (2) those who dissect the tonsil out, claiming that with any form of guillotine no one can be certain of entirely removing any tonsil; (3) those who combine partial dissection with the use of a guillotine.

To my mind the existence of this third group is evidence that groups (1) and (2) are both in error, in that they go to unjustifiable extremes. The truth lies between, and I venture to submit that the following view is hardly available.

A certain proportion (which I will not here attempt to specify) of tonsils are removable, complete in capsules, by certain guillotine methods. The remainder are not, and have to be removed by some form of dissection, which requires more practice and dexterity than the former. No one, therefore, should claim to be prepared to deal with any and every tonsil with which he is confronted, unless he is practised in enucleation by dissection.

POISONING DUE TO BELLADONNA PLASTER.

T. C., aged 37, a strongly-built, muscular labourer, was first seen at 11 a.m. complaining of pain in the back. Nothing abnormal was discovered, and as the pulse and temperature were normal and he was anxious to continue his work, a belladonna plaster about 6 in. by 4½ in. was applied, and he went back to his employment.

At 2 p.m. he was carried in on a stretcher, struggling and being held by two men. The skin was harsh, dry and reddened, pupils dilated, pulse 130, and respirations 40; he was delirious and semi-conscious; the temperature was unobtainable on account of his movements. The plaster was immediately removed and he was admitted to hospital, where he remained more or less in the same condition until 9 p.m., when he became quieter and sank into an uneasy sleep, the pulse then being 115 and respirations 30. The temperature was 97.5°. The following morning he was much better, though the tongue and lips were dry and furred, and he was still slightly incoherent in speech. He had no recollection of what had occurred, and though he declared that he felt quite well he refused solid food, and was with difficulty persuaded to take any nourishment. The bowels responded to an aperient, and the urine passed naturally contained no albumin, blood, or casts.

Two days later the only sign remaining was slightly enlarged pupils responding slowly to accommodation; the patient left feeling perfectly well—pulse, respiration, and skin condition being normal. There was no history of any previous fits or similar illness, and I have no doubt that the symptoms were directly due to an overdose of atropine absorbed through the skin from the plaster. The case is of interest in showing the danger which may arise from this cause in susceptible persons.

HALAZONE FOR WATER STERILIZATION.

(Report to the Medical Research Committee.)

In the *BRITISH MEDICAL JOURNAL*, May 26th, Dakin and Dunham describe a new chlorine compound, *p*-sulphondichloraminobenzoic acid, suitable for sterilizing small individual quantities of drinking water. For convenience they call the new substance halazone. The chief advantage claimed is that it can be put up in tablets, which, when kept in amber glass bottles, lose strength only very slowly. The dose for ordinary water is given as one tablet to an imperial quart, and for heavily polluted water two tablets to a quart, the time of exposure in both instances to be thirty minutes. Samples of halazone tablets supplied by the Medical Research Committee were subjected to various tests.

Weight of Tablets.—From Dakin and Dunham's article it appears that the tablets are intended to weigh approximately 0.1 gram each. The weight of tablets from three lots was found to vary: the weight of tablets from lot K was 0.075 gram each, from lot M 0.098 gram, and from lot N 0.104 gram. The variation in the weight of the tablets is an error which should be corrected.

Solubility.—One or two tablets in 38 oz. of water contained in an aluminium water bottle, carried by a marching soldier, were always found completely dissolved within ten minutes: with an enamelled water bottle holding 40 oz. of water complete solution required twelve minutes.

Taste.—Taste experiments were conducted with tap water only. One tablet to a quart was not detected by any one of three observers. Two tablets to a quart were detected as taste by two observers, and as taste and smell by the third. In respect to taste halazone seems to be identical with chlorine from other sources, and with certain waters would no doubt form chlorine compounds, having an objectionable taste.

Keeping Qualities.—Tablets kept in a bottle under ordinary laboratory conditions were tested at the end of six weeks, and were found quite as effective as usual in sterilizing various types of water, the ordinary doses being used.

Mode of Action.—Water treated with this compound gives the ordinary starch iodide test for free chlorine, and the efficiency of the sterilization may be forecasted from the amount of free chlorine remaining after thirty minutes' exposure, as judged by the depth of blue colour with starch and iodide. Ordinary tap water treated with a double dose smells and tastes of chlorine. Hydrogen sulphide and organic matter interfere with sterilization by halazone as by chlorine from bleaching powder.

From these considerations it seems probable that halazone, when added to water, liberates free chlorine, which

acts for sterilizing purposes in the same way as chlorine from other sources.

Bacteriological Tests.

The efficiency of halazone was tested on soft, moderately hard, and very hard waters, on tap water polluted with urine, fresh sewage, and stale sewage, and on a contaminated surface water, to all of which cultures of *B. coli* and *B. typhosus* were added.

It was found that one tablet of halazone per quart is sufficient to render safe a clear water of low organic content. Two tablets per quart will, in most cases, render safe any water likely to be consumed. Hardness does not appear to interfere with the sterilizing action.

Conclusions.

1. Halazone is a satisfactory chlorine compound for the sterilization of small individual quantities of drinking water. Its mode of action is the same as that of chlorine from other sources.

2. The tablets are readily soluble and do not lose strength rapidly.

Reports of Societies.

MADNESS AND UNSOUNDNESS OF MIND.

At the seventy-sixth annual meeting of the Medico-Psychological Association of Great Britain and Ireland on July 25th, in the rooms of the Medical Society of London, under the presidency of Lieut.-Colonel DAVID C. THOMSON, M.D., R.A.M.C., Dr. CHARLES MERCIER recalled that it was little more than twenty-five years since he first promulgated the doctrine that madness and unsoundness of mind were not the same thing; that madness included more than unsoundness of mind, and that unsoundness of mind very often occurred in the sane; indeed, that it was one of the most frequent disorders of the sane. It was only about twenty-seven years since he first published this view, and already the Medico-Psychological Association was beginning to grasp it! Yet the remainder of the profession looked upon the alienist branch as obscurantist and unwilling to adopt new ideas, a view that he hoped Dr. Steen's recent paper on hallucinations in the sane would do much to dispel. Dr. Mercier said that the last time he brought his view before the association it was practically laughed out of court; he was told it would mean handing over the treatment of madness to the police. Three years ago, when he brought his view before the Royal Society of Medicine, it met with a similar fate. In spite of the fact that he had clearly defined it at the meeting of the Royal Society of Medicine already referred to, and no worthy argument had been urged against it, in the third edition of Dr. Craig's *Psychological Medicine* the doctrine was not even mentioned, and its author stated that insanity could not be defined. To regard insanity as disorder of mind was an imperfect, inadequate, lopsided, halting, superficial, ignorant, childish, belated, obscurantist, and stupid view to take. Those who contended that madness was a disorder of mind alone did not perceive the difference between mind and conduct, between thinking and feeling on the one hand, and talking and acting on the other. To regard madness as disorder of conduct was as great an advance upon regarding it as disorder of mind, as viewing it as disorder of mind was an advance upon regarding madness as a possession of the devil. Dr. Mercier's next thesis was that there were many disorders of mind which were quite compatible with sanity. Dr. Steen showed in his recent paper that hallucination was a disorder of mind, and could occur in the sane. There were many other disorders of mind which could not be regarded as insanity. One was tinnitus, which was, in fact, an aural hallucination; it was a perception of sound arising in the mind without any justification in the shape of an impression on the organs of sense. Tinnitus was a disorder of the mind. It was true that a physiological basis for it could often be found in disease of the middle or internal ear, but disease of those parts was not tinnitus. Madness was not the same thing as disease of the brain; cerebral tumour and

cerebral haemorrhage were diseases of brain, but they did not constitute madness; they might exist without discoverable trace of madness. It was not provable, but it might be that in every case of madness there was disorder or disease of mind, but madness was certainly not the same thing as disorder or disease of mind; even if it were, we could never examine it; but it was proved that in every case of madness there was disorder of conduct. When a man was certified as mad, it was because of something he had said or done, and saying and doing were conduct. In the absence of any failure or defect in conduct, attention was not called to him. Whatever the state of a person's mind might be, he was not considered mad if he behaved in every respect like a sane person. It was upon conduct that the alienist founded his judgement, and behaviour could be directly observed. The alienist put into his certificate "facts observed by ourselves at the time of examination." A disorder of brain or a disorder of mind could not be observed; the delusion a person suffered from could be neither seen nor heard. All that could be done was to hear the utterance of it, and that utterance was conduct.

Sir GEORGE SAVAGE thought the author had one or two obsessions on this subject; for instance, he considered that the association, as a whole, did not agree with him that insanity and unsoundness of mind were not the same thing. But Sir George, in his article in Allbutt's *System of Medicine*, urged the same point. There was much unsoundness of mind which did not seriously affect the relation of the individual to his circumstances. Mandsley, years before, expressed much the same view. Moxon, when asked for a definition of insanity, retorted, "How can you define a negation?" One could define sanity, but not insanity. Hughlings Jackson's writings made one realize that any one of the factors of mind could be disordered without producing a corresponding disorder of conduct, and so long as a modification of the cerebral condition did not interfere with conduct it must be admitted that insanity was not present. Swinburne could scarcely be said to be of sound mind; he was an epileptic, and yet he had a brilliant intellect. Persons with a double personality might be very insane in one of the states.

Dr. HAYES NEWINGTON, though he did not agree with Dr. Mercier, did not feel capable of giving a definition of insanity. In the certificate, insanity and unsoundness of mind were not regarded as convertible terms, as shown by the important word "or," meaning that the person concerned might be suffering from either; there was a choice between them. When the milder term "unsoundness of mind" was used, it was held to mean a state not so advanced as to merit the term "insanity." He preferred the old phraseology, that insanity was a disorder of mind.

Dr. JAMES STEWART agreed that the word "insanity" implied a negation, and thought it was impossible to hope to include the various forms of mental disorder in one definition. Alienists were agreed on the point so strongly emphasized by Dr. Mercier, that a person declared insane was one who showed a disorder of conduct; but the term implied more, and the extent to which it did so was thoroughly well understood by the practitioners of the speciality.

Sir BRYAN DONKIN expressed his agreement with the contention of Dr. Mercier, and did not consider that he regarded disorder of conduct and insanity as convertible terms. Dr. Mercier's contention was that disorder of conduct was a necessary element in the concept of insanity, and that without such disorder of conduct the person could not be pronounced insane.

Dr. E. S. PASMORE contended that the first indication of the advent of insanity was an alteration in the person's conduct; that had been a guiding principle in his own practice as an alienist. It was a matter of comparison—the contrast of present conduct with what was observed at an earlier date. A person with an hallucination of hearing or of sight might lead a quite normal life, and it was not until the hallucination was believed by the person to concern himself intimately that alteration of conduct commenced.

Dr. J. G. SOUTAR said the subject had been debated ever since insanity had been discussed. All alienists were agreed as to what insanity was when they encountered it, but the difficulty was to put into words an adequate

definition. The practical point to be determined with regard to a person whose sanity was in question owing to antisocial conduct, was whether such conduct was the result of mental disorder. That was to proceed beyond the mere consideration of the person's conduct. Histories showed that patients fell into certain mental attitudes which tended to result in certain types of conduct. For a long time patients struggled against the logical outcome of their mental condition. He believed that a considerable time before a patient would admit it in words, and long before he committed any antisocial act, he was subject to a definite mental attitude, and it was the duty of the physician, by watching small indications, to detect this tendency and seek to obviate the impending evil by suitable treatment. The alienist did not focus his attention and his decision on the saying of a wrong word or the doing of a little wrong thing, but studied the patient as a whole. The feature on which Dr. Mercier had insisted was only one of the criteria; it was not the whole matter.

Dr. MERCIER promised to send a full reply to the association's journal.

Rebelsus.

WAR NEUROLOGY.

Oorlogsneurologie (War Neurology),¹ by T. VAN SCHELVEN, is a summary in five chapters of much of the recently published neurological experiences of German and French military doctors. From the chapters on injuries of the peripheral nerves, spinal cord, and brain, we are left with the impression that in Germany not much advance has been made in treatment, and but little in diagnosis, in spite of the large amount of material which the war has provided. It is stated that the variety of injuries of the peripheral nerves has been extraordinarily great, and that there is much risk of nerve injury being overlooked unless definitely sought for. Nerve injuries may be followed by nutritional disturbances (muscle degeneration, decalcification of bone, etc.), and by functional disturbances (vasomotor upsets and irregular action of sweat glands). These effects are more frequent and pronounced when a nerve is caught in scar tissue, and conduction is incompletely interrupted, than when it is completely divided. "In other words, trophic and vasomotor disturbances are rather signs of nerve irritation than of nerve paralysis." Accordingly, excision of the strangled part of the nerve and union of the divided ends might be followed in a few days by the disappearance of pain and of trophic and vasomotor symptoms. Complete recovery after suture may take eighteen months in the case of the sciatic nerve. The author holds that if a nerve is incompletely divided, the healthy nerve fibres must not be touched, and that suture is, therefore, out of the question, since it might "sacrifice" the sound fibres. Operation for freeing the nerve from compression gave good results. On the other hand, in more than 10 per cent. of cases nerve suture was not followed by regeneration. Clinical examination alone can determine whether operation is necessary. The nerve may be recovering spontaneously, though there is no indication of this. The difficulties of diagnosis are discussed at length. Of injuries of the spinal cord it is said that they remain as formidable as ever. Expert examination, even with the aid of radiography and lumbar puncture, often left it doubtful whether the condition was concussion, compression, or complete division of the cord. Therefore some surgeons performed exploratory laminectomy at once, risking sepsis; others waited three to four days or eight to ten weeks, risking permanent damage from removable compression. The worst complication is urinary decomposition, best avoided by sterile catheterization thrice daily, and the exhibition of hexamine. As a shot which grazes the surface of the skull may splinter the internal bony surface so as to tear the dura mater or penetrate the brain, an apparently trivial wound may have a disastrous effect, and in war practice trephining for slight grazes of the external table must be the rule. Different operations for the

removal of a foreign body from the brain are described, and it is asserted that after trephining the patient must wait at least fourteen days before being moved, or he will die. Results are unsatisfactory—cures are "surgical, not functional."

In the last chapter the possible effects, mechanical and psychical, on the nervous system of explosions which cause no visible external injury to the patient are discussed.

THE PREVENTION OF FUTURE WARS.

The settlement of personal disputes by force of arms is gradually giving place to more rational means, but national quarrels are still determined by methods of barbarism scientifically applied. Under modern conditions the loss, even to the victors, would seem to outweigh the gain. To seek for some system by which such a catastrophe may in future be averted is a task worthy of the best efforts of practical men of all shades of opinion and of all nationalities.

The formation of the American League to Enforce Peace has been followed by the establishment in this country of the League of Nations Society, the first meeting of which was held in Westminster, under the presidency of Viscount Bryce, last May. Simultaneously a series of *Proposals for the Prevention of Future Wars*² has been published, to which Lord Bryce and many other leaders of thought have contributed; the object is to start certain fundamental principles as a basis of discussion.

Briefly, it may be said that the first essential is the formation of a healthy public opinion throughout all civilized countries. An international agreement between all or most of the Powers of both hemispheres might through moral and economic forces lead to the establishment of arbitration. The anger of nations, like that of individuals, is apt to be cooled by delay. The establishment of an international moratorium would give time for anger to subside and for a better understanding on all lands of the points at issue.

The scheme, as outlined by Lord Bryce, is a further development of that of the Hague Conference, but tends towards definite action whereby the public opinion of the combined States could be enforced by other means than those of warfare. The time is not yet ripe for action. The difficulties of organization are many and call for the best thoughts of practical minds from every quarter of the globe.

NOTES ON BOOKS.

THOSE—and they must be many—who, while recognizing the value of the central aim of Pacifism,³ are impatient of the blindness of its typical adherents to awkward facts, may be recommended to study Dr. NORDENTOFF'S attempt to outline a practical programme for the gradual supersession of the appeal to force as a means of settling international disputes, as well as for the systematic study of the economic and other causes of war, with a view to their ultimate removal. No sane man will quarrel with Dr. Nordentoff's brand of pacifism, seeing that in the closing sentence of his book he frankly admits that "a just decision through war is to be preferred to an unjust decision through peace."

Dr. W. M. BARTON has brought together a quantity of useful information in his little book on the testing of vital functions.⁴ It contains readable summaries of the various clinical and laboratory methods that have been devised for testing the functional integrity of such organs as the liver, kidney, pancreas, heart, and the chief ductless glands. Naturally, such a book must partake of the nature of a compilation; the literature dealing with such tests as these has become very extensive during the last two decades, and Dr. Barton has made excellent use of much of it. He also gives in most cases some indication of the value that is to be attached to the results of the tests he describes, for which clinicians will be grateful.

British Medical Journal.

SATURDAY, AUGUST 11TH, 1917.

AFTER THREE YEARS: THE MEDICAL SERVICES.

THE Prime Minister last Saturday (August 4th), the third anniversary of the declaration of war between Germany and this country, said that the German leaders now realize that this time their plot has miscarried, and say, "there will be peace shortly, but the war will be resumed in ten years"; they desire a bad peace such as "goes on and on, staggering from one war to another." The Prime Minister appealed to us to be "the generation that manfully, courageously, resolutely eliminated war from among the tragedies of human life." The President of the United States has said the same thing in other words to his countrymen. So has M. Ribot to France. Mr. Gerard, who was the Ambassador of the United States to Berlin for the four years preceding the delivery to him of the six-hour ultimatum which precipitated the outbreak of war between his country and Germany, has a recent experience of the mind of Germans and their rulers which no one to-day can pretend to rival. In the foreword to the book of his experiences, which the *Daily Telegraph* is having cabled from New York, he says: "We are warring against a nation whose poets and professors, whose pedagogues and whose priests have united in stirring its people to a white pitch of hatred, first against Russia, then against England, and now against America." He tells his countrymen that they stand in great peril, and only the exercise of ruthless realism can win this war. If Germany wins it will mean, in his opinion, the triumph of those who believe not only in war as a national industry, not only in war for itself, but in war as a high and noble occupation. Unless Germany is beaten, every nation will be compelled to turn itself into an armed camp until the German autocracy either brings the whole world under its dominion or is for ever wiped out as a form of government. Finally, he warns us that no one should believe that Germany will break under starvation or make peace because of revolution.

We must assume, therefore, that these statesmen accept neither the prevalent peace talk nor the whispered pessimism of the last few weeks, both perhaps due to German intrigues, but look forward to a continuance of the war for some indeterminate but long period beyond Lord Kitchener's three years. It behoves, then, the whole community, and every section of it for itself, with open eyes candidly to take stock of the situation. Every calling has its own problems; those which confront the medical profession are serious; and every delay in taking steps to meet them renders it more difficult to find a satisfactory solution.

The Central Medical War Committee has now been compelled to take the serious step of notifying to the Secretary of State for War that after a careful survey of the whole of England and Wales it is of opinion that no more medical men can be called upon to take commissions in the R.A.M.C. without seriously endangering the supply of doctors for the treatment of the civil community, and that any further depletion can only be effected on the responsibility of the

Government after careful comparison of the military and civil needs.¹

The Central Medical War Committee has only made this notification to the War Office after full consideration and when it could no longer be delayed. It speaks from an accumulated experience which goes back before the first Military Service Act was passed, and we venture to express the hope that the Army Medical Department will realize that administrative action under the second Military Service Act, such as that taken in April last, will not meet the circumstances or be an efficient solution of the problem with which the country is confronted.

The Review of Exceptions Act, if it has done no other good, must have served to convince the public that, in respect of recruiting generally, Great Britain, as one witness said, has "got down very close to the bone," and may cause the readier credence to be given to the reiterated statement that it will not be possible to meet the demands of the army for medical officers if they are continued on the same scale as in the past. Already the civilian population is suffering, the middle class perhaps especially, but the industrial also, from a dearth of doctors. The long duration of the war has operated in two ways to deplete the ranks of the medical profession. The great armies the country now maintains are detaining a large proportion of the more active members of the profession, men young or in the prime of life. The elder men who remain to attend to the needs of the civilian population are striving each to do the work of two or three; many have broken down, and the proportion must increase. Each such breakdown should be reckoned a war casualty, and unhappily not a few would have to be added to the list of "died on service."

The military authorities know that their demands for combatant recruits must be limited, for though the reservoir from which they can be drawn was deep, the drain upon it has been so large that it is now becoming shallow. This must be one of the chief governing facts in their strategical plans. The analogous state of things with regard to medical recruits should equally be a governing fact in the strategy of our medical military administrators.

What are the courses open to the War Cabinet? It may take up the proposal for the mobilization of the profession on a principle analogous to that of substitution instituted by the National Service Department. It was a principle favoured by the professional committees six months ago, but it was even then realized that it would not achieve the desired end on a voluntary basis, and much has happened since to cause it to be regarded with less favour than at that time. The conference called last March by the Director-General of National Service to consider the organization of the medical profession with a view to meeting the needs of the military and civil population came, we understood, to the conclusion that legislation would be necessary for any compulsory scheme. Of any other result of the conference the public knows nothing, but the idea of making substitute service compulsory on other callings seems to have been dropped, and legislation to apply it to the medical profession would be certain to arouse strong opposition on political grounds--and not only within the profession.

Another course, and one which we hope will be taken by the War Cabinet, is to look carefully into the use now made by the army of the large number of medical men in its ranks. The Under Secretary of State for War, in declining to institute a departmental inquiry, said that the Army Council was alive to the

¹ The full text of the letter is published in the SUPPLEMENT, p. 35.

situation and that the Higher Command was satisfied that all medical practitioners were being used in the best way. This is not the impression or experience of many of the officers themselves, and we would ask whether the Higher Command has made any such thorough investigation of the military side as the professional committees have made of the civil. The time has come for a decision with regard to the respective demands of the army and the civil community for services essential to both.

This decision cannot be made by the army without consultation with representatives of the civil medical profession and with the government departments concerned. The Army Council is not in possession of information essential to a decision, but it has at its disposal, in the statutory professional committees, bodies which have accumulated information and experience. Our hope is that the Army Medical Department will realize that it is within its power, by consulting with these committees, to find a solution of the difficulty, by frank discussion between members, military and civil, of the profession itself.

THE MIND OF THE SOLDIER.

THE medical service on the Western front is automatic. Its operation is so quiet and easy that the movement goes almost unheeded. On June 7th, the day the Messines Ridge was carried, ambulance trains were entering Charing Cross at 2.15 in the afternoon. The action began at daybreak, and persons in London returning from luncheon saw the casualties from the battle being off-loaded. On Easter Monday Vimy Ridge was attacked at 5.30 in the morning. Within an hour the wounded were coming down. Shortly after noon the battle was over, and by 4 o'clock the field was clear. In one case the feat was performed by the Royal Army Medical Corps and in the other by the Canadian Army Medical Corps, both services working with internal and combined harmony.

Such events as these are merely a part, or rather an interruption, of the regular work of the medical service. Its main business is to keep the army in a state of health. As a result we are presented with the spectacle, for the first time in the history of war, of an army without sickness, save for those minor ailments to which the military as well as the civil population is prone.

Yet, as the years pass, and the war proceeds, new problems present themselves to the medical service. Those problems concern the mind of the soldier rather than his body; they are difficult because they are new, and have in them that element of subtlety which is always inherent in mental conditions.

This warfare itself is a new thing in its continuity and intensity apart from its duration. There have been longer wars. The Seven Years' War lasted seven years; the Thirty Years' War lasted thirty years, but in those days armies went into winter quarters; a siege was a leisurely affair; a battle was the business of a morning; billets were undisturbed by far-reaching artillery, and "reserve" meant rest. Behind the line there was an approach to civil life, and even certain domestic amenities were not wanting. On the night before Waterloo "sounds of revelry" were heard, and highly placed officers shared in revels such as are now reserved for subalterns, and then only upon the too rare occasions when they have leave.

Upon the soldiers whose home is within these islands this new warfare bears hardly, but when they have leave they go home to familiar scenes, to fields in which they played, to village streets in which every

house has a meaning, it may be to a club or even to a public-house reminiscent of innocent cheer in the far-off days of peace. Above all, they experience the soft compliance of their womenkind, which eases their labouring spirit from the hard control of military discipline. There is, in short, a break in the life of poverty, temperance, and obedience. But for soldiers who come from overseas there are none of these ameliorations. England to them is London, where they are lonely, in spite of the official hostels which are opened for their entertainment, and no private hospitality can charm away their longings for their own. They have only two happy moments: when their leave begins and when it ends. The German soldier is better off. When he has leave he, too, goes home.

Of these peculiar hardships there is no legitimate complaint. All enlisted for three years or "the duration." The three years are up, but the end is not yet. The military authorities are under no primary obligation to save a man alive. They are obliged to make the best of him whilst he is yet living, but they are not fulfilling that obligation when they permit an officer to continue at his post when his mind is overstrained to the point of breaking.

This war is carried on by civilians. Many of its problems are civil problems, such as arise in the conduct of any business. The nation is the army, and the medical service is face to face with precisely those conditions which confront it in private practice. The service itself is carried on by practitioners of medicine, who have by no means abdicated their functions merely because they wear uniform clothing. They, above all men, are aware that there is a point beyond which the mind must not be strained, if it is to recover its resiliency.

With the approach of a fourth winter a system should be devised by which officers shall have automatic relief, a system as simple as in civil life, under which a business man takes a holiday and returns regenerated to his task. The reasons are identical. He takes a holiday to save his business. Under present conditions an officer can go sick, but the system is so cumbersome that when he goes sick he is already dead. He applies to his medical officer; he passes through a field ambulance, he is evacuated to a casualty clearing station, and having run the gauntlet of innumerable medical officers he may eventually reach the base, and having appeared before numerous boards he will resume his journey to the front again; but to accomplish this purpose his malady must be of so obvious a nature that it can be detected at a casual glance. Otherwise he falls into the category of neurasthenia, neuritis, myalgia or shell shock, all of which have a sinister significance for the sensitive man. His career is ended, and that is not what the army wants, for the experience which he has gained during laborious years is lost to the service.

These observations apply to officers of all ranks in the fighting line, especially to battalion commanders and the heads of the auxiliary services, men who have heavy responsibilities, and are for long periods under fire, who have gained an experience which can be discarded only with ultimate loss. Junior officers are more carefully watched over, and a considerate commander is always alert lest they be overstrained.

The heaviest trial a medical officer has to endure is the private interview with a combatant officer who feels himself on the point of breaking. These men are tortured by the fear, in most cases groundless, but none the less real to them, lest in a moment of forgetfulness they may bring loss upon the service,

and dishonour upon themselves and their families. In civil life these consultations are a large part of private practice. There is nothing furtive or shameful about them, and the medical man consulted applies the remedy of rest. In the army he is helpless, and the officer returns to his duty, with the risk of disaster to himself, to the men under his command, and to the operations in which he is engaged. A keen-eyed medical officer may observe these signs of mental deterioration, but he can do nothing. The merest expression of solicitude on his part may be interpreted as a suspicion of incompetence, especially in cases where the suspicion is justified.

An attempt has been made to meet this condition by the grant of leave "on compassionate grounds." A soldier who asks for compassion is already finished. He may obtain some sinecure job in which his moral deteriorates rather than improves, but in either case his usefulness is impaired by the suggestion of stigma which is attached to such posts, whereas a period of rest and freedom would restore him to full vigour.

An officer who is fit to command a battalion or its equivalent is fit to be taken at his word when he signifies that he needs a rest. His opinion might be confirmed privately by one of the more highly specialized consultants in the medical service, and the way should be made smooth and easy for him. He should not be compelled to pass through the usual official channel, which is necessarily narrow and rigid. His case should receive instant and sympathetic consideration, not especially in his own interest but for the good of the service. Such an arrangement would loosen up the service. It would afford the second in command a chance to show his capacity. It would mean a move up for every one below and give to all a change of work, which would make for the mental health of the whole.

The Australian Government has been impressed by these considerations, and, we understand, has an arrangement in view for returning to their homes on furlough all officers and men who have served "from the first." Besides, the good of the service, the good of the family, and therefore the good of the country, is involved. Men—and women too—forget because they must, and not because they will. The difficulties of time and space which confront the Australians are not so serious in the case of Canada. A three months' furlough for officers in the higher commands would be a simple affair. It is one of the most obvious preparations for a long war. The pick of the Canadian medical profession is overseas. The Canadian Government has always shown itself to be peculiarly sympathetic towards that branch of the service. Surgeon-General Foster knows, as no one else knows, the full burden of life at the front, for he has borne it in his own spirit for two years from Ypres to the Somme. We commend to him and to his consultants on purely medical grounds—and it is upon those grounds alone we are entitled to urge a suggestion—the case of these courageous and faithful soldiers, lest they be tried beyond endurance by a fourth winter in the trenches.

The like considerations apply to the other overseas contingents with equal force. They apply also, though with the mitigations we have noted, to the soldier whose home is within the British Isles. The principle of a holiday for the soldier should be recognized, especially for the man who has to shoulder heavy responsibilities from the pressure of which his mind can never be for a moment free while he is on service. An interval of rest, of change from the obsession of his war surroundings, should come not because he is on the verge of a breakdown, but in the routine of sound military administration.

SIR ALFRED KEOGH.

THE newspapers during the last few days have been full of attacks and rumours of attacks on Army Medical Administration, which, it was hinted, might even involve the retirement from his present position of the Director-General in this country. We would view the resignation of Sir Alfred Keogh with a feeling akin to despair of the future of the organization and reorganization of army medical affairs. We are glad to say that so far from there being any likelihood of this, there is every probability of Sir Alfred Keogh carrying on the great work he has done in the building up of a service for the care of the sick and wounded which has never been paralleled in the history of warfare. Any one who has experience of the work being done in the military hospitals throughout the country must be aware that the care of our wounded and sick brought from overseas is of a standard rarely equalled even at the best of our civilian hospitals, which are the best in Europe. Moreover, the development of the medical work from a purely scientific standpoint gives cause for amazement. So much of this is due to Sir Alfred Keogh's personal influence with his colleagues of the civilian profession that the criticisms, tinged as they are with obvious political bias, do not move us. There are matters, to which we refer elsewhere, calling for prompt attention from a man of his breadth of mind and true professional instincts, and we believe that the more closely the Army Medical Department works with the civilian doctors, who now constitute eleven-twelfths of the Army Medical Services, the better for everybody—the Director-General himself, the services over which he presides, and for the country at this critical period. In our judgement Sir Alfred Keogh would do well to establish in his office a new department for dealing with the innumerable difficult questions affecting those members of the R.A.M.C. who have been withdrawn from civil life to serve the army, and to place at the head of it an officer possessing long experience of civilian methods and practice, and the intensive military experience which so many territorial medical officers have gained during three years of active service. Such an officer would understand the difficulties of individual territorial and temporary officers, would be able to represent their troubles to the Director-General, and would be in a position to act as a sympathetic intermediary between him and the professional committees or any joint subcommittee they may delegate for the purpose.

OMISSIONS FROM THE BRITISH PHARMACOPOEIA.

THE serious shortage in the supplies of sugar and glycerin available for medicinal purposes, which has already occasioned grave inconvenience, has now culminated in a notice issued by the General Medical Council and published in the SUPPLEMENT, temporarily deleting from the current edition of the *British Pharmacopoeia* a considerable number of galenic preparations containing these substances. The intention of this proceeding is, of course, to diminish as far as possible the unnecessary prescribing of those galenicals containing sugar and glycerin which are relatively unimportant or for which substitutes can be devised, and it is to be hoped that the profession will aid this very desirable object as far as practicable by abstaining from prescribing the deleted articles. The list of these, however, contains several important and widely used preparations for which it is very necessary that efficient substitutes should be provided as soon as possible, such as compound tincture of rhubarb and compound liquorice powder. It is obviously very desirable that the substitutes should be standardized preparations of known composition, and we understand that a supplement of the *British Pharmaceutical Codex* will shortly be issued (probably in the course of a few weeks) containing a comprehensive list of alternative preparations suitable for prescribing in

place of those now removed from the *British Pharmacopoeia*: the only precaution then necessary will be to add the letters B.P.C. to the name of the preparation. In this connexion, however, it may be noted that there is really comparatively little practical difference between preparations containing sugar and those containing sugar substitutes, since the latter substances are now largely used in food preparations while the supplies are very limited; it seems desirable, therefore, that the use of such preparations which do not possess any actual medicinal value should, as far as possible, be avoided. For the moment the existing stocks are probably sufficient to supply the demand for those preparations for which no proper substitutes are now in existence, but as the distribution of these stocks will, no doubt, quickly become very unequal—with consequent loss of uniformity in dispensing—it is evident that substitutes should in all cases be prescribed as soon as they are available.

THE EFFECT OF THE LIQUOR CONTROL REGULATIONS.

IN a written answer to a question asked in the House of Commons, on July 17th, Sir Worthington Evans supplied a table of weekly averages of convictions for drunkenness in areas which had been scheduled under the Liquor Control Regulations up to the end of 1916. The table is arranged in the following way: The weekly average number of convictions in each area for the four weeks prior to the coming into effect of the order is shown, then the average number throughout the whole of 1916 or such part of that year as was later than the making of the order, and then the weekly average for each successive period of four weeks down to that ending on June 17th, 1917. The general results for the whole of Great Britain are as follows: The average for the four weeks before the order was 3,956; for 1916 (the part of the year subsequent to the order) 2,434; and for the successive periods of four weeks, beginning with that ending December 3rd, 1916: 2,500, 2,697, 2,127, 1,945, 1,755, 1,420, 1,333, 1,352. The form of this return is not well chosen for the purpose of statistical comparisons; it would have been better to show the number of convictions for corresponding weeks before and after the enforcement of the order, but that the trend is downwards cannot be disputed. The *prima facie* inference is, of course, that the Control Board's regulations have had the desired effect, and this may quite well be the fact. At the same time, it is necessary to remember that statistics of this kind are ambiguous. The population of Great Britain in the scheduled areas has undergone great changes both in age and sex constitution owing to the war, while the same factor may have affected the police administration. A district from which a considerable proportion of men of military age has been withdrawn and to which large numbers of women have been attracted, would be likely to return fewer police convictions for drunkenness, while darkened streets and a reduced police force might be expected to lead to fewer arrests. It seems difficult to assess the value of these objections. In an article published by the *Daily Telegraph* on July 31st a chart is given showing total convictions for drunkenness (women), deaths from overlying, cases of attempted suicide (women), and deaths from alcoholism (women) for each year from 1911 to 1916 (inclusive). In every case there has been a considerable decline since 1914. The convictions for drunkenness declined from 37,311 in 1914 to 21,245 in 1916, and deaths from overlying fell from 1,233 to 744. The numbers of convictions among women for the whole country are not subject to the same criticism as those for all convictions, so far as variations of the age and sex constitution are concerned. The other data, particularly deaths from alcoholism, are open to many objections and have little statistical value. We think that the general impression created—namely, that there has been a sensible

decline in the overt manifestations of alcoholic intemperance—may be accepted, but it is desirable to have the subject further investigated, and no doubt the scientific advisory committee appointed some months ago by the Central Control Board will pay attention to the point.

A SOCIAL PIONEER.

WHEN the time comes to appraise the work of those pioneers of social reform whose high aims and unwearied enthusiasm were so memorable a factor of English life in the later years of the nineteenth century, few names will shine with a brighter lustre than that of the late Canon Barnett, founder of Toynbee Hall. For thirty-three years he and Mrs. Barnett, who survives him, lived and worked in Whitechapel, first for twenty years in St. Jude's Vicarage, then, after the building of Toynbee Hall in 1884, for thirteen years in its Warden's Lodge, "surrounded with the splendid body of Residents and Associates who were the first to bring honour to the Settlement movement." Of Canon and Mrs. Barnett it has been justly said that "a rare combination of idealism and practical capacity and a complete sympathy of aim made their thirty-three years' life and labour in Whitechapel singularly fruitful in the numerous efforts to which they set their hands. . . . To an astonished world they preached the gospel of University Extension Teaching, and co-operation and co-ordination among social workers, especially in the distribution of charity; and advocated causes considered then so quixotic as the higher education of pupil teachers, fortnights in the country for the poorest children, and free concerts, books, and picture galleries. By a simplicity and a directness amounting to genius they quickly won to their side some of the best heads and hearts in the metropolis, who shared their faith that the humblest ought to have an opportunity of drawing inspiration from the best that literature, art, and music could supply." On the eve of the summer meeting now in progress (August 3rd to August 17th) under her presidency at the Institute of the Hampstead Garden Suburb, devoted to after the war problems of reconstruction, Mrs. Barnett by a happy inspiration issued a memorial volume comprising some sermons, papers, letters, and aphorisms of her lamented husband, together with a brief biographical introduction. For Canon Barnett Christianity was not merely a doctrine to be professed but pre-eminently a life to be lived. It involved the recognition of universal goodwill and its expression in mutual service as the supreme ideal for individuals and nations. Hence this little volume of selections from his writings and sayings, aptly entitled *Vision and Service*, carries the weight pertaining to the words of those who practise what they preach. Many readers will turn with special interest to the Canon's last sermon on the resurrection and national policy, preached in Westminster Abbey on March 30th, 1913, to which, with its note of solemn warning and its undercurrent of grave foreboding, subsequent events have supplied so poignant a commentary. But all the contents of the pamphlet speak the faith and enthusiasm of a true and constant lover of mankind. The little book is embellished by a portrait of Canon Barnett, and a reproduction of Watts's "Love and Death," a replica copy of which, presented by the artist, hangs in the hall of the institute at the Hampstead Garden Suburb.

FLIES AND COLOURED LIGHT.

THERE are more ways of killing a dog than choking him with butter, says the adage, and the remark applies also to flies. One of the neatest, cleanest, and most scientific modes of getting rid of flies is founded on the observation that their visual apparatus is apparently only sensitive to white light, most of the primary colours producing on them the same effect as darkness. According to MM. Galaine and Houlbert,¹ the fly's retina is not impressed at

¹ *C. R. Acad. des Sciences*, p. 132.

all by violet and indigo, a little apparently, and that little disagreeably, by blue and green; yellow and orange are better borne, and reds are not perceived at all. Now for the application of these data to the problem of fly riddance. In a room with only one window the ordinary panes are replaced by light-blue glass, one being made to open when required in order to admit white light. These observers found that flies were attracted into the room through the open window, became restless as soon as the window was closed and only blue light prevailed, and then became lethargic, as in the dark. If at this juncture the movable pane were thrown open, admitting white light, they promptly availed themselves of the opportunity to escape. This experiment, repeated with green glass, yielded approximately the same results, but those with yellow were less conclusive. When there are two or more windows, those on one side of the room should be opened while the others are closed. Flies wandering into the room turn tail as soon as they perceive the blue light. A further advantage of the blue panes is that they arrest most of the heat rays. It is true that the employment of blue glass diminishes the illuminating powers of the light rays, but this can in a certain degree be overcome by employing a mosaic of blue, green, yellow, and even red glass. It is to be noted that flies are comparatively unobtrusive in churches provided with plenty of coloured stained-glass windows.

FARM COLONIES FOR THE TUBERCULOUS.

IN the JOURNAL of July 21st we made brief reference to the contribution by Sir R. W. Philip to a discussion on farm colonies at the annual meeting of the National Association for the Prevention of Consumption. It appears that there is a growing misapprehension among the public as to the relative functions of the sanatorium and the farm colony, leading to an ill-informed demand that the former should be replaced by the latter. In the course of his remarks on the place of the farm colony in the antituberculosis campaign Sir Robert Philip dealt especially with this and kindred mistaken ideas. He pointed out that the farm colony is no new idea, nor is it the last word in relation to tuberculosis. In essence it is an extension of treatment, on simpler lines, for patients incompletely cured at a sanatorium. It is in no sense a panacea for tuberculosis. The arrest of lung tuberculosis takes time, and for permanent reparation a long time is needed. In the slow development of tuberculosis lies the chief difficulty of diagnosis, and in the slow healing of tuberculosis lies the chief difficulty of treatment. Lack of appreciation of the natural history of the disease is the main cause of disappointment in the results of treatment. Somehow or other the Insurance Act has led people to imagine that, given three months' sanatorium treatment, cure may be expected. Such hopes are, of course, vain, and those who built faith upon them are naturally discontented. Hence the swing of the lay pendulum towards the farm colony and the need for Sir Robert Philip's reminder that the various tuberculosis institutions are not mutually competing. It is foolish, he says, to pit one against the other, to discuss the relative value of the dispensary and the sanatorium, and, again, of the farm colony, as if they were rival agencies. Each institution has its proper place in a sound antituberculosis programme. The one institution does not replace the other. They are mutually complementary. He defines the purpose of the farm colony: it is to serve those tuberculous patients whose disease, after varying periods at the sanatorium, has been almost or completely arrested, but who remain evidently liable to a relapse. It is dangerous and uneconomical for such persons to return to their ordinary avocations, while they require more prolonged care and guidance than is possible at the sanatorium. At the farm colony the patient merges in the colonist; residence there, under the medical eye, is a test period, in which the neuromuscular tissues, poisoned by the tuberculous toxins,

steadily recover strength and tone, and the system gradually accommodates itself to the conditions of ordinary working life. For those to whom return to their old occupations at any time would mean certain relapse it is a period of education and training in new pursuits. The life is of the simplest, and the cost relatively low. A colony is a post-graduate school for character no less than for physique, the primary curriculum being passed through at the sanatorium. Hence the colonist must be selected on definite principles so that the colony may not be a dumping ground for all sorts of tuberculous patients at every stage of the disease. Sir Robert Philip's warning is timely.

OBSELETE TUBERCULOUS LESIONS IN THE LUNGS OF ADULTS.

WHILE working over the well-worn subject of the site of tuberculous lesions in the lungs, Opie¹ has broken fresh ground by showing, in the course of an investigation "on focal pulmonary tuberculosis of children and adults," that the healed or healing lesions found in the lungs of so many children and nearly all adults have characters which serve to distinguish them from the progressive pulmonary tuberculosis of adults. They are identical with the pulmonary tuberculosis of infancy and early childhood, which may occur in any part of the lung, is not more often localized in the apices than elsewhere, and, indeed, tends to occur in the middle lobe of the right lung or in the corresponding part of the upper lobe in the left lung. In infancy there is little fibrosis around the lesion, but with advancing age this follows; the pulmonary lesion does not often show cavities, and these when present are small; it is accompanied by massive tuberculosis of the regional lymphatic glands, and resembles tuberculosis in a freshly infected animal. In the lungs of adults, on the other hand, there are two sharply definable forms of tuberculosis: (1) The apical, or that commonly recognized, which tends to spread diffusely into the lung, is not accompanied by caseation or calcification of the regional lymphatic glands, and though often fatal may become obsolete; (2) focal, or identical with that seen in infancy and early childhood, which is found in at least 92 per cent. of all adults, and may be acquired between the ages of 2 and 18 years. Almost all human beings are thus spontaneously vaccinated with tuberculosis before they reach adult life, and the apical form, if it subsequently occurs, is due to a second infection. From the presence of calcium salts in the focal lesions, x-ray plates may detect the healed lesions when not otherwise obvious in thin sections of the lungs. The paper, which is illustrated by nine skiagrams, is based on *post-mortem* examinations of 50 adults (3 dying from pulmonary tuberculosis) and 93 children (11 dying from tuberculosis). In the bodies of those dying from other diseases tuberculosis was found in 47 adults and 11 children. Of the 93 children 43 were under one year.

SPIROCHAETOSIS AND WEIL'S DISEASE.

AMONG the diseases which have become prominent during the war special interest attaches to spirochaetosis icterohaemorrhagica, which, though usually, is not invariably accompanied by jaundice; in the latter event, it may, from the prominence of nervous symptoms, resemble meningitis, though the cerebro-spinal fluid of such patients may be normal (Bloch and Hébert²). Another possible cause of confusion about anicteric cases of spirochaetosis icterohaemorrhagica is that the Wassermann test for syphilis is often positive (Costa and Troisier³). Early in the year there was some correspondence between Sir Frederick Taylor, chairman of the committee of the Royal College of Physicians on the nomenclature of diseases

¹ E. L. Opie, *Journ. Exper. Med.*, Baltimore, 1917, xxv, 855-876.

² Bloch and Hébert: *Bull. et mém. Soc. Méd. des Hôp. de Paris*, 1917, 3^e sér., xli, 69.

³ Costa and Troisier: *Compt. rend. Soc. Biol.*, Paris, 1917, lxxv, 195.

(1906-17), and Dr. A. F. Hurst in the *Lancet*¹ about the title "Weil's disease" previously applied to cases of acute febrile infective jaundice now proved to be due to this form of spirochaetosis; this eponymous title has the advantage of brevity, but accuracy and considerations of priority, for what they may be worth, can be urged in support of the adoption of the more cumbersome terms of "jaundice spirochaetal (icterohaemorrhagica)" and of spirochaetosis icterohaemorrhagica for the form without jaundice. The new edition of the *Nomenclature of Diseases*, now in the press, will, we understand, contain the term "spirochaetosis"; under "jaundice" two forms of infectious nature will be recognized—(a) bacillary, and (b) spirochaetal—the latter comprising spirochaetosis haemorrhagica and spirochaetosis recurrens (recurrent fever). Unfortunately, the comparatively manageable names spirochaetal jaundice and spirochaetosis are not sufficiently definite to eliminate syphilitic infection. There is a way out of the difficulty which so far does not seem to have been considered and necessarily has the drawback of coining a fresh word; Noguchi finds that the *Spirochaeta icterohaemorrhagiae* differs in certain characteristics from other spirochaetes, and argues that it constitutes a distinct genus for which he suggests the name *Leptospira*; it would therefore appear that leptospiral jaundice and leptospirosis might be both euphonious and distinctive. As already mentioned, there are some reasons—and these are quite apart from any antagonism engendered by an enemy name—against the retention of the term "Weil's disease" as a synonym for infection with *Spirochaeta icterohaemorrhagiae*. In the first place, the most obvious feature of the disease described by Weil was jaundice, which is not present in all cases of this infection. Secondly, as regards the thorny question of priority, while it is not possible to be certain if the disorder described by authors at different periods is the same, it has been pointed out² that Larrey was familiar with the condition in Cairo in 1800, and that Lancereaux, Landouzy, A. Mathieu and others also anticipated Weil. Further, Valassopoulos, whose interesting report on bilious typhus or infective-febrile jaundice, which he identified with the so-called Weil's disease, read before the first Egyptian Congress of Medicine in 1902, has perhaps been rather neglected, recognized the disease in 1876 in Alexandria, where it first appeared after the sewers were constructed in 1870. He considered that Griesinger's bilious typhoid described in 1853 was not, as most writers on the subject have assumed, the same as Weil's disease. But the difficulty of identifying as the same disease disorders described at different times and places by various writers is illustrated by the curious circumstance that whereas Valassopoulos considered the febrile infective jaundice of Egypt to be the disease described by Weil, which is now proved to be due to infection with *Spirochaeta icterohaemorrhagiae*, the febrile jaundice recently seen at Gallipoli and in Egypt among our troops, and presumably the same as that long known in Egypt, appears, so far as is known, to be due to some duodenal infection allied to that of paratyphoid A, and not spirochaetal, thus differing from the jaundice seen on the Western front. It therefore seems reasonable to regard acute febrile infective jaundice as a syndrome which may be due to several causes and not a disease, and to conclude that the question of priority, though an interesting historical exercise, has not much bearing on its nomenclature.

In connexion with the recent visit of the King and Queen to France, His Majesty has appointed Surgeon-General Sir Arthur Sloggett, K.C.B., K.C.M.G., Director-General Army Medical Service in France, to be a Knight Commander of the Royal Victorian Order.

At the annual meeting of the Medico-Psychological Association of Great Britain and Ireland on July 25th, Mr. John Mayne Colles, LL.D., K.C., J.P., Registrar in Lunacy in Ireland, and Dr. Alexander Reid Urquhart, late physician-superintendent of James Murray's Royal Asylum, Perth, were elected honorary members. We regret to have to record that Dr. Urquhart died a week later. A resolution congratulating the President, Lieutenant Colonel D. C. Thomson, R.A.M.C., on the conclusion of another year's presidency was unanimously adopted on the motion of Dr. Hayes Newington, whose death we have the sorrow to record elsewhere in this issue of the *JOURNAL*. At the same meeting the Gaskell Prize, consisting of fifty guineas and a gold medal, was awarded to Dr. James Cowan Woods, Major R.A.M.C., of the Priory, Roehampton. The work next in order of merit, that of Dr. Monrad-Krohn, was considered to be of such high merit that it was decided to present him with fifteen guineas and a replica of the medal in silver.

Medical Notes in Parliament.

The Royal Army Medical Corps.

MAJOR DAVID DAVIES asked the Prime Minister, on August 2nd, whether, in view of the shortage of doctors to meet the civil requirements of the nation, he would institute an inquiry into the administration and organization of the Royal Army Medical Corps in order to ascertain whether the services of medical officers who had joined the army were utilized to the fullest extent. Mr. Macpherson (Under Secretary for War) replied: The Army Council are fully alive to the shortage of medical officers and are watchful that the fullest use is made of all medical officers employed by the army, but it is not proposed to institute at the moment any inquiry while active operations are in progress which might dislocate and militate against the effective administration of the forces in the field.

Major Davies: Does the War Office intend to do anything? Mr. Macpherson: Well, the business of the War Office is to consider the demand made by the Higher Command.

Mr. Pringle: Has a Departmental Committee considered the extent to which the services of medical practitioners now in the army are being utilized? Mr. Macpherson: No; but my information is that the officers of the Higher Command are satisfied that there are none of the medical practitioners who are not being used in the best way.

Sir Garrod Thomas: Is the hon. gentleman aware that civilian medical practitioners who joined the army twelve or eighteen months ago, and have been abroad, have only done real medical work for a few hours during the whole of that long period? Mr. Macpherson: I do not know where the hon. member gets his facts, but I am glad in a way that doctors are largely unemployed at the front; it shows that the casualties are few. At the same time, at any given moment the casualties may be very severe and very numerous.

Mr. Pringle: Is my hon. friend not aware that a large part of the time of these medical men is taken up with work which is not medical, and which could be done by laymen who have had no medical experience? Mr. Macpherson did not take up this inquiry.

Major Davies asked, on August 6th, whether in the organization of the Royal Army Medical Corps a certain number of fully qualified medical men were employed to supervise the mechanical and horse transport of the ambulance and other Royal Army Corps units at the front; and whether, in view of the shortage of civilian doctors, he would take steps to allocate this particular work to officers who were not qualified medical practitioners. Mr. Macpherson replied: In all motor ambulance convoys there is attached an officer of the Army Service Corps whose duties are to look after the mechanical transport; but an officer of the Royal Army Medical Corps is necessarily in command of this as of all other medical units for the care of the wounded. In the case of field ambulances, a warrant officer of the Army Service Corps is attached to superintend the motor ambulance and horse wagons.

¹ *Lancet*, 1917, i, 200, 238, 317.

² Martin and Pettit: *Bull. Acad. Méd.*, Paris, 1916, 3 sér., lxxiv, 247.

Army Medical Service Administration.—In reply to Major David Davies, on August 8th, Mr. Macpherson said that evidence was given by the British Medical Association as well as by others before the committee presided over by Mr. Churchill, and it would not be conducive to the efficiency of the service nor the successful prosecution of the war to initiate such an inquiry as was suggested into the Army Medical Service while the war was in progress. The Secretary of State some little time ago arranged for certain eminent medical men to visit France for the purpose of satisfying him that the medical services were on a sound basis. The visit of the committee would take place when the operations now in progress admitted of the carrying out of useful inquiries.

Military and Civilian Medical Services.—Major David Davies, on August 7th, asked whether the Prime Minister's attention had been called to the fact that there was no department responsible for the provision of doctors to meet the medical requirements of the civilian population; whether the War Office had called up civilian doctors irrespective of civilian needs; that owing to the defective organization of the Royal Army Medical Corps the services of doctors who had joined the army were not utilized to the fullest extent; and whether he would appoint a competent authority to adjudicate between the competing claims of the Royal Army Medical Corps and the civilian population, as has already been done in the case of agriculture. Mr. Macpherson: There is a committee appointed for this purpose under the Military Service Act, which is the competent authority under that Act. I think my honourable and gallant friend is under a misapprehension in supposing that the War Office calls up doctors irrespective of civil needs, or that the fullest and best use is not made of the doctors serving on the various fronts. Major Davies: By what department was this committee appointed? Mr. Macpherson: By the War Office. He added, in reply to Mr. Chancellor, that he did not think any estimate had been formed of the number of qualified medical men serving as privates in the ranks, but every inducement was being given to qualified men in the ranks to take commissions in the Royal Army Medical Corps.

The Status of the Army Medical Department in the War Office.—Major David Davies asked Mr. Macpherson whether, in view of the responsibility devolving upon the Director-General of the Army Medical Service for the health and sanitation of the British armies, the time had arrived when this branch of the War Office should no longer form part of the Adjutant-General's department, but should be given the status of a separate department at the War Office, whose responsible head should be a member of the Army Council. Mr. Macpherson replied, in a written answer, that Lord Derby considered this question some time ago, and decided that the present was not an opportune moment at which to reopen discussion on a matter of organization of this importance, which had been decided some years ago after the fullest investigation of all the relevant arguments. With that decision Lord Derby was still in the fullest agreement.

Colonel Carter's Position.

In reply to a question by Mr. Gilbert, the Secretary of State for India (Mr. Montagu) said that Lieut.-Colonel Carter, I.M.S., was at present employed under the Admiralty in the equipment of hospital ships. Under Indian regulations an officer placed on special duty in this country drew somewhat less than the full pay of his substantive appointment in India. Lieut.-Colonel Carter's deputation pay—£1,057 10s. a year—was accordingly less than that attached to the last appointment which he held in India—namely, £1,360 a year. Mr. Montagu added that he was in communication with the Government of India on the subject of recognition of Lieut.-Colonel Carter's services.

Mr. Hogge asked whether Lieut.-Colonel Carter, who was responsible for exposing the scandal of Mesopotamia, ought to suffer, either financially or in any other way, as the result of his action. Sir J. D. Rees asked whether officers in the Indian services did not regard serving at home for a time at slightly lower pay as a privilege and an advantage. Mr. Montagu replied that it was because he recognized that the gallant officer's services deserved recognition that he was communicating with the Government of India as to his promotion or other special recognition. The difference between service in England and service in India must, according to the Regulations, obviously—and he thought rightly—be represented by

some difference in emolument. In further reply to Mr. Gilbert as to the reason why Lieut.-Colonel Carter was transferred to the Admiralty, Mr. Montagu said that he had shown himself peculiarly well equipped to the service he was rendering to the Admiralty. He was loaned to the Admiralty for the purpose of assisting in the equipment of hospital ships.

Colonel Yate asked whether, in making the recommendation for the promotion of Colonel Carter, Mr. Montagu would bear in mind that Colonel Carter was in independent charge of a hospital ship running between Bombay and Basra, and that consequently he had to bear none of the heat and burden of the day of going down the river Tigris in charge of the wounded, which was borne by the other officers of the Indian Medical Service, and would Mr. Montagu recommend officers of like rank in the Indian Medical Service for promotion as well as Colonel Carter? Sir George Toulmin: They did not render the same service.

Vaccination in India.—Mr. Snowden asked the Secretary of State for India the question as to setting up machinery in India whereby genuine objectors to vaccination could be exempted from the compulsory law as in England, Scotland, and Wales. Mr. Pratt (for Mr. Montagu, who was seeking re-election on his appointment) said the question and the suggestion would be referred to the Government of India.

Army Medical Re-examination Committee.

The Select Committee of the House of Commons on the Medical Service (Review of Exceptions) Act, 1917, presented a "special report" on August 2nd, which recommended that the whole organization of recruiting by medical boards and of the medical examination and re-examination, should be removed from the War Office and placed under civilian control, and pending action on this: (1) That all men waiting to be called up for military service, or holding a certificate of temporary or conditional exemption, may appeal to an Appeal Tribunal, and such Tribunal, if it thinks fit, may order a re-examination of such men by a medical or special medical board. (2) That all attested men should have the same rights of appeal as unattested men. (3) That all men who have been called up since April 5th, 1917, and are still in the United Kingdom, should have the right to appear before, and be examined by, an invaliding medical board.

There was little new in the resumed evidence of Surgeon-General Julian before the Committee on August 2nd. It was chiefly about documents the witness had put before the Committee. On the old question of classification by medical tribunals, General Julian said that the president of a medical tribunal did the classification, but he did it on advice. Thus the other doctors shared in the decision. The witness did not credit an allegation that an old soldier's discharge papers had been taken from him, believing that inquiry would give an answer to such "an unheard-of" story. In some cases there were difficulties about medical history sheets, which were vitally important. Touching Class C3 men, the witness mentioned that an Army Council instruction was issued by the War Office on July 27th. This provided that entries should be made of men fit to work under domestic conditions if their health permitted; the tribunals were also requested to say whether a man was fit to follow his own trade.

The War Cabinet's Decision on the Principle.

Sir Maurice Levy asked on August 7th whether the Government intended to give effect to the proposals with regard to the administration of the Military Service (Review of Exceptions) Act which Lord Derby had announced his readiness to accept.

Mr. Bonar Law replied that if the question referred to certain promises made by the Secretary of State for War to the Select Committee, orders to give effect to them had already been issued, the Army Council Instruction in which they were embodied having previously been shown to the Chairman of the Committee and by him to the Committee, to whom the proposals commended themselves as carrying out the pledges. If, on the other hand, the reference was to the larger question of the transfer of the responsibility of recruiting, this matter had been before the War Cabinet, which had accepted the change in principle. The details had still to be determined.

We understand that no decision has yet been reached, and the positive assertion that the work will be turned over to the National Service Department is at least premature.

DR. WILLIAM H. WELCH has resigned the post of head of the department of pathology at Johns Hopkins University to take up that of director of the School of Hygiene and Public Health. He is succeeded in the former appointment by Dr. W. G. McCallum, of Columbia University.

THE WAR.

THE RECENT OPERATIONS ABOUT YPRES.

THE information which reaches us with regard to the work of the medical service during the recent operations near Ypres shows that though it was much impeded by the almost continuous rain, varied by an occasional deluge, it was carried out with a degree of success from the point of view of the wounded for which we could hardly have hoped. One of the greatest dangers is the aggravation of the shock due to the wound itself by exposure to cold and wet. The mud everywhere, but especially between the regimental aid posts and the advanced dressing stations of the field ambulances, was amazing, and the labour involved in stretcher-carrying enormous. It took practically six bearers to a stretcher, instead of what is now the almost normal—two. Moreover, the relays had to be numerous, for now that we have advanced so far road-making is hampered by the water-logged condition of the ground.

However, once back to the advanced dressing station, things were comparatively easy, for, apart from ambulances, there are tram-lines, broad-gauge lines, from the collecting posts back to the walking-wounded main dressing stations, and lying cases main dressing stations. Consequently things medical moved well despite the floods of rain. The same tale could, perhaps, not have been told had not the greater part of the casualties occurred during the first twenty-four hours, when the weather was comparatively dry. Afterwards there were merely dribbles of wounded. They included quite a large number of Germans, who are being treated in all ways precisely as if they were Allied Force casualties. The difficulties in clearing the field of action of casualties have since, no doubt, been formidable, as for all other forms of military work.

Had it not been for the rain the work of the main dressing stations would have been light, as they are not desired to do operating or any but essential dressings. Owing to the weather, however, their work was very heavy, for practically all cases arrived soaked in mud, and had to be refitted with pyjama or other dry clothing, blankets, and clean stretchers, before dispatch on the remainder of their journey to the casualty clearing stations. Such attention is of great benefit to the patients, and also does much to relieve the strain on the staffs of the casualty clearing stations and to hasten the moment at which the necessary operations can be undertaken.

The casualty clearing stations are very numerous and have a larger number of operating teams than ever, so there has probably again been an increase in the ratio of operations undertaken to the wounded. These early operations, of course, add immensely to the chances of recovery. Casualty clearing stations as a whole seem now to have specialized to a considerable extent, some dealing almost solely with head cases, others with abdominal injuries, etc. Taking them as a whole, the type of case has been light; in particular thigh cases have not figured largely on the list; the casualties are reported to have arrived in very good condition as a rule, though there has been plenty of work for the staffs of the observation wards, which are now to be found at all casualty clearing stations as a matter of routine. It seems likely, therefore, that the net result of the medical arrangements in this offensive will not fall below the very high level attained in the Messines affair.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Died on Service.

TEMPORARY SURGEON E. S. CALTHROP, M.B., B.S., R.N.

Dr. Edward Spencer Calthrop died on July 30th of toxic neuritis. He was the second son of Mr. and Mrs. Edward Calthrop, and received his medical education at Charing Cross Hospital. He took the diplomas of M.R.C.S., L.R.C.P., Lond. in 1909, and graduated M.B., B.S. Lond. in the following year. After holding the office of house-

surgeon at Charing Cross Hospital he saw service with the Turkish Red Crescent and also with the Bulgarian Field Corps during the Balkan war. He was to have served with Sir Ernest Shackleton on the polar expedition but obtained instead a commission in the Royal Navy and was attached to the Royal Naval Division. He spoke French well and had a writing knowledge of Turkish and Russian.

ARMY.

Killed in Action.

MAJOR W. D. KIRKLAND, A.A.M.C.

Major William Duncan Kirkland, Australian Army Medical Corps, was killed in action on July 22nd. He was the elder son of the late Dr. Kirkland of Lithgow, New South Wales. He received the Military Cross on June 10th, 1917.

CAPTAIN G. S. PIRIE, R.A.M.C.

Captain George Stephen Pirie, R.A.M.C., was killed in action on July 24th. He was the second son of the late George Pirie of Affcullen, Plumstead, Cape Town, and of Leopard's Vley, Cape Colony, and was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1914. He took a commission as lieutenant in the Special Reserve of the R.A.M.C. on January 2nd, 1915, and was promoted to captain after a year's service, and on January 11th, 1917, accepted a permanent commission in the R.A.M.C. as lieutenant, with the temporary rank of captain. He had served in the 29th Division in Gallipoli, where he was wounded, and since December, 1915, in France. He had twice been mentioned in dispatches. He was attached to the East Surrey Regiment when killed.

CAPTAIN W. A. SNEATH, M.C., R.A.M.C.

Captain W. A. Sneath, M.C., R.A.M.C., whose death from wounds was reported in the BRITISH MEDICAL JOURNAL of August 4th, was there stated to be a temporary officer. He took a permanent commission in the R.A.M.C. from January 11th, 1917.

Died on Service.

LIEUT.-COLONEL J. H. HORTON, D.S.O., I.M.S.

Lieut.-Colonel James Henry Horton, D.S.O., I.M.S., was reported as having died on active service, in the casualty list published on August 2nd. He was born on December 27th, 1871, the son of Major J. Horton of Woolwich, was educated at Guy's Hospital, where he gained the Arthur Durham prize in 1891, and took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1895. After filling the post of house-physician at Guy's and at the Royal Bethlem Hospital successively, he went to India as a special plague medical officer. He was one of the four plague officers who accepted commissions in the I.M.S. as lieutenant from January 29th, 1902, and while at Netley gained the Marshall Webb medal and prize. He became captain on January 29th, 1905, major on July 29th, 1913, and was specially promoted brevet lieutenant-colonel on December 21st, 1916. He served in East Africa in 1902, in the operations in Somaliland, was present in the action at Jidballi, was mentioned in dispatches (*London Gazette*, September 2nd, 1904), and gained the medal with two clasps and the D.S.O.; on the North-West Frontier of India, in the operations in the Mohmand country in 1908, medal with clasp; and as surgeon to the British Red Cross Society in the Balkan war of 1912, medal with clasp. He also had the fourth class of the Order of St. George and St. Vladimir of Russia. On March 17th, 1908, he was posted as medical officer of the 14th Bengal Cavalry, and at the beginning of the present war was appointed to the command of the 126th Indian Field Ambulance.

MAJOR J. AITKEN, R.A.M.C.(T.F.).

Major James Aitken, R.A.M.C.(T.F.), died at Yorkhill Military Hospital, Glasgow, on July 29th. He was the son of the late Mr. William Aitken of Glasgow, and was educated at Glasgow University, where he graduated M.B. and C.M. in 1891, after which he went into practice at Ilford, Essex, where he was honorary surgeon to the Merchant Seamen's Orphanage. He took a commission in the auxiliary forces on May 29th, 1901, had been surgeon-captain in the 4th Battalion of the Essex Regiment, and became major in the 1st East Anglian (Norwich) Brigade of Royal Field Artillery on August 5th, 1914.

CAPTAIN R. H. BHARUCHA, I.M.S.

Captain Rustam Hormusji Bharucha, I.M.S., was reported as having died on active service, in the casualty list published on August 2nd. He was born on July 2nd, 1884, educated at the Grant Medical College, Bombay, where he graduated as L.M. and S., and at University College, London, and took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1909. He entered the I.M.S. as lieutenant on January 29th, 1910, and became captain on January 29th, 1913. When the war began he was medical officer of the 86th Carnatic Infantry.

CAPTAIN R. H. DRENNAN, R.A.M.C.

Captain Robert Hugh Drennan, R.A.M.C., died at Gravesend recently, aged 51. He was the youngest son of the late Mr. James Drennan, J.P., of Carse Hall, Limavady, Ireland, and was educated at Edinburgh University, where he graduated M.B. and C.M. in 1892. He was in practice at Gravesend till he took a temporary commission as lieutenant in the R.A.M.C. towards the end of 1915, being promoted to captain after a year's service.

Wounded.

Lieut.-Colonel R. P. Lewis, R.A.M.C.

Captain R. R. G. Atkins, R.A.M.C. (temporary).

Captain R. Dow, R.A.M.C. (temporary).

Captain W. J. Evans, R.A.M.C. (temporary).

Captain H. S. G. Haji, I.M.S.

Captain J. L. Hamilton, R.A.M.C. (T.F.).

Captain J. W. Macdonald, R.A.M.C. (temporary).

Captain P. J. Matthews, R.A.M.C. (temporary).

Captain L. Meakin, R.A.M.C. (temporary).

Captain R. A. Stark, R.A.M.C. (T.F.).

Captain D. S. Twigg, R.A.M.C. (T.F.).

Lieutenant T. Archdeacon, R.A.M.C. (temporary).

Lieutenant A. A. Henderson, R.A.M.C. (temporary).

Lieutenant and Quartermaster O'Hara, R.A.M.C.

DEATHS AMONG SONS OF MEDICAL MEN.

Ross, William Stuart, Lieutenant Border Regiment, second son of Dr. Douglas Ross of Brighton, killed July 23rd, aged 25. He was educated at Brighton College, where he was in both cricket and football teams, and at St. Catherine's College, Cambridge, where he gained a classical scholarship, and graduated B.A. in the classical tripos of 1914. When the war began he enlisted in the Public Schools Battalion, and got his commission in the Border Regiment on November 13th, 1914. He had served at Gallipoli, where he was wounded at Suvla Bay, in Egypt, and in France, where he took part in the capture of Thiepval and of the Messines Ridge.

Wheeler, Percival Francis Crommelin d'Erf, Captain Dorsetshire Regiment, attached Royal Flying Corps, killed while flying on duty on July 24th. He was the eldest son of Captain d'Erf Wheeler, R.A.M.C., formerly of the English Hospital, Jerusalem, now attached to the Egyptian Expeditionary Force. He was born at Jerusalem on April 5th, 1894, and was educated at Clare House, Beckenham, and Trent College. In May, 1913, he was gazetted to the 1st Dorsetshire Regiment. He went to France in September, 1914, in charge of a draft from his regiment, and was severely wounded at La Bassée a month later. He was promoted to the rank of captain early in 1915, and in December, 1915, was sent to Mesopotamia in charge of a draft of the Dorsets, where he served for eight months, having much valuable work to his record, in spite of several attacks of malaria; but finally he was sent to Bombay to hospital with a severe attack of paratyphoid. He returned to England on January 1st, 1917, and underwent a course of training for the Royal Flying Corps, and was on the eve of receiving his wings when he met his death while flying on duty at an aerodrome in England. As a soldier and an airman a brilliant future was predicted for him, and his death is a great loss to his profession.

MEDICAL STUDENT.

Nisbet, John Stewart, Private R.A.M.C., second son of Provost Nisbet, J.P., of Denny, died of dysentery at Lindi, East Africa, on July 17th, aged 22. He was a medical student at Glasgow University in 1914-15, enlisted in the Scottish Horse, and was subsequently transferred to the R.A.M.C.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

NOTES.

OFFICERS COMMENDED.

THE following medical officers are included in a further list of names brought to the notice of the Secretary of State for War for valuable services rendered in connexion with the war:

Surgeon-General Sir David Bruce, C.B., F.R.S., M.B., F.R.C.P., A.M.S.

Colonel R. D. Rudolf, C.A.M.C.

Lieut.-Colonels: J. A. Amyot, C.A.M.C., G. E. Armstrong, C.A.M.C., F. W. Begbie, R.A.M.C., J. T. Clarke, C.A.M.C., S. A. M. Copeman, M.D., F.R.S., T.D., R.A.M.C., W. H. Delaney, C.A.M.C., D. Donald, C.A.M.C., C. H. Gilmour, C.A.M.C., P. G. Goldsmith, C.A.M.C., J. Gordon, A.A.M.C., J. McCombe, C.A.M.C., H. E. Munroe, C.A.M.C., H. S. Newland, A.A.M.C., Sir A. Newsholme, K.C.B., R.A.M.C., H. R. G. Poate, A.A.M.C., H. A. Powell, C.M.G., A.A.M.C., R. Raikes, C.A.M.C., H. M. Robertson, C.A.M.C., C. L. Starr, C.A.M.C., J. Tidbury, M.D., R.A.M.C., A. L. A. Webb, C.M.G., R.A.M.C.

Temporary honorary Lieut.-Colonels: H. R. Kenwood, M.B., R.A.M.C. (Major R.A.M.C.), J. Robertson, M.D., R.A.M.C.

Majors (temporary Lieut.-Colonels): H. T. D. Acland, N.Z.M.C., F. T. Bowerbank, N.Z.M.C., A. S. Brewis, N.Z.M.C., R. M. Carter, F.R.C.S.E., I.M.S.

Majors: S. H. McCoy, C.A.M.C., D. S. Mackenzie, A.A.M.C., J. D. Morgan, C.A.M.C., R. E. Wodehouse, C.A.M.C.

Temporary honorary Major T. G. M. Hine, M.D., R.A.M.C.

Captains (temporary Majors): W. Bruce, N.Z.M.C., W. H. Unwin, N.Z.M.C.

Captains: A. B. Chandler, C.A.M.C., W. V. Corbett, R.A.M.C., N. H. M. Dalston, N.Z.M.C., W. J. Enright, C.A.M.C., D. E. Fenwick, N.Z.M.C., G. E. O. Fenwick, N.Z.M.C., A. G. R. Foulerton, F.R.C.S., R.A.M.C., H. G. Gibson, R.A.M.C., F. L. Golla, M.B., R.A.M.C., T. F. Graham, C.A.M.C., H. C. Hall, C.A.M.C., R. H. Hogg, N.Z.M.C., W. B. MacDermott, C.A.M.C., W. C. Smales, D.S.O., R.A.M.C., W. Tweedy, N.Z.M.C., W. S. Wallis, N.Z.M.C.

Temporary Captains: H. S. Raper, M.B., R.A.M.C., F. R. Seymour, R.A.M.C.

Temporary honorary Captain W. M. Flack, R.A.M.C.

Lieutenant H. E. Stevens, A.A.M.C.

Quartermasters and honorary Majors: A. Bruce, R.A.M.C., J. Watkins, R.A.M.C.

Quartermasters and honorary Lieutenants: A. Harwood, R.A.M.C., J. W. Willsheer, R.A.M.C.

Temporary Quartermaster and honorary Lieutenant J. Ritchie, R.A.M.C.

Ireland.

THE TUBERCULOSIS PROBLEM.

At the twenty-fifth annual general meeting of the Royal National Hospital for Consumption, held in Dublin on July 30th, the medical report for 1916, signed by Dr. W. L. Crofton, Mr. F. K. Cahill, F.R.C.S.I., and Mr. F. O'B. Kennedy, resident medical officer, was presented. In a paper on the tuberculosis problem Dr. W. L. Crofton said that, roughly, about 70,000 people die of tuberculosis in the British Isles in each year, about 50,000 of them from tuberculosis of the lungs. In 1915 there were in Ireland 9,625 deaths from the disease, of which 7,547 were from disease of the lungs. Nearly 73 per cent. of these deaths occurred in persons between the ages of 15 and 45 years. The deaths from the disease in Ireland represented a rate of 2.2 per 1,000 of the population, as compared with a rate of 1.5 for England and Wales and 1.6 for Scotland. It was generally recognized that the large majority of people were at some time or another infected with tuberculosis, and it must be assumed that the natural resistance of 80 per cent. of the population was able to overcome the infection. If the resistance of the remaining fraction of the population could be made normal the problem would be solved, and only sporadic cases, produced by specially virulent infection, would occur. The commonest cause of tuberculous infections in children was the bovine strain of the bacillus conveyed to them in milk from tuberculous cows. Dr. Crofton held that each city should have its own municipal dairy of tested and immunized cows. A pure milk supply was as important as a pure water supply. The chief source of the human type bacillus was the expectoration of people with tuberculous disease, and the proper way to stop the spread of infection from this cause was to isolate patients until their sputum ceased to contain tubercle bacilli, which meant until they were cured or died. The lowering of the resistance of the individual, which allowed the disease to develop, might be due to (1) bad hygienic surroundings; (2) infection with other microbes; (3) inheritance of a low resistance; (4) the overcoming of the normal resistance by a virulent or continuous infection. The only method of insuring an adequate resistance of the individual against a prevailing infection was by inoculating him with a vaccine of the causative microbe. Tuberculosis would not be stamped out until the resistance of every member of the community was raised in this way. A beginning should be made with members of families whose parents were tuberculous or in which tuberculosis had occurred. The sanatorium

method had been shown by Karl Pearson to be a complete failure. Some had supplemented it by inoculating the patient with tuberculin; in many cases, especially in the early days of its use, this had done actual harm, owing to ignorance of the fundamental principles of immunization. Even in skilled hands its success had been only partial, because tuberculosis of the lungs in these climates was practically always a mixed infection, the lungs being invaded before, at the same time, and after by other microbes, as well as the tubercle bacillus. No more than a partial success could therefore be expected when only a part of the cause of the disease was being attacked. By attacking all the microbes infecting a given patient with a chemical germicide combined with inoculation of vaccines, not only of the tubercle bacillus, but also of the mixed infections, Dr. Crofton had obtained encouraging results and had been able to arrest the disease, not only in the early cases, but also in many acute and advanced cases. The results obtained at the Royal National Hospital for Consumption in Ireland were from three to five times as good in the different stages of the disease as before these methods of treatment were used. Institutions should be of two kinds: first, hospitals near the large centres of population for the treatment of well-established cases, where the patients could receive nursing and treatment until they were strong enough to go to the second kind of hospital, which should be of the nature of a convalescent home, where they would undergo a hardening process. The first kind of hospital should have wards tacitly set apart for hopeless cases. Every dispensary doctor should have a special course of instruction in the methods, should have a special nurse or nurses to help him, and should hold dispensaries for tuberculous patients at suitable short intervals. In every county there should be a hospital and convalescent home, with sufficient beds and resident staffs to satisfy the institutional needs of the county, to which should be attached as visiting physician a county tuberculosis officer, who would act as consulting physician to the dispensary doctors. In the big cities the tuberculosis dispensaries should have whole-time medical officers and nurses; while attached to the hospitals should be institutions for chemical research, where the materials for diagnosis and treatment for each province could be prepared.

England and Wales.

THE HEALTH OF LONDON.

WE noted last week the appearance of the report for 1916 of the medical officer of health and school medical officer of the administrative county of London.¹ Dr. Hamer begins his introduction with an interesting "talk about the weather." Early workers in epidemiology, he reminds us, attached great, perhaps undue, importance to meteorology. Their successors, with the modern reverence for laboratory methods and for inquiries into regions hitherto unexplored, have neglected somewhat the knowledge carefully and laboriously acquired in earlier days. The type of distribution of rainfall over the metropolitan area during the past seven years has, it appears, exercised a marked influence for good upon the public health. According to this view, the phenomenal weather conditions of recent years, which reached "high water mark" in 1916, account far more than is generally realized for the lower infant mortality and the reduced death-rate from epidemic throat diseases, diphtheria, typhoid fever, and epidemic diarrhoea, and also for the freedom from the ordinary nuisances prejudicial to health. But beyond the abnormal weather conditions, the disturbances due to a great European war had their effect upon the death and sickness rates for 1916. Restricted freedom of communication with foreign countries, brought about by the war, has diminished the spread of infectious disease; against this must be set the depletion of sanitary staffs due to the same cause. Looking towards the future, Dr. Hamer points out that trying seasons will come round again, peace conditions will once again favour spread of infectious

disease; the need for maintaining the sanitary service becomes more evident every month.

Vital Statistics.

The total civil population of London county in the middle of 1916, as estimated by the Registrar-General, was 4,237,387. Dr. Hamer considers that this estimate may be too low. Since 1914 it is certain that the gradual cessation of building operations has practically put an end to all outward movement from London towards the outlying districts, while decreased railway services and increased fares have tended to set up an opposite movement towards the centre. Furthermore, the births in London during 1915-1916 exceeded the deaths by nearly 67,000; and to this increase of population must be added thousands of refugees who have come to live within the county. Against these factors must be set the decrease due to enlistment, which, in Dr. Hamer's opinion, probably did no more than maintain an even balance up to the end of 1916. With so many uncertain factors it is evident that the estimates of population upon which mortality and sickness rates are calculated cannot altogether be relied on.

The marriages registered in London numbered about 43,800, as compared with 58,354 in 1915—an abnormal year—and 43,373 in 1914. The calculation of a marriage-rate for comparison with pre-war figures is difficult owing to the fact that the marriages included those on active service, while the published estimates of population relate to civilians only. The Registrar-General's calculation for 1916 is 19 per 1,000.

The births in London county numbered 99,336, as against 102,117 in 1915, and 109,952 in 1914. The Registrar-General's estimated rate is 21.5 per 1,000 for 1916, which stands for comparison with 25.0 in the pre-war period 1909-13.

The deaths among the civil population in London during 1916 numbered 62,325, as compared with 72,393 and 66,037 in the two previous years. The Registrar-General calculates the death-rate for 1916 at 14.7 per 1,000. The withdrawal of males of military age from the total gives a misleading aspect to this rate; had there been no war the death-rate in 1916, calculated on a normal population, would have been below the rate of 14.6 recorded in 1914, and would not, Dr. Hamer believes, have greatly exceeded the record rate for 1912 of 13.6.

Infant Mortality.

The deaths during the first year of life in London during 1916 numbered 8,864, or 89 per 1,000 births. In 1915 and in 1914 the rates were 112 and 104. The infant mortality for 1916 is the lowest ever recorded in the county, the previous record being 91 in 1912. A preponderating share in this result is attributed to the favourable conditions of moderate summer temperature. There were nearly 750 fewer deaths from diarrhoea and enteritis in children under one year of age than in the previous year. The reduction of infant deaths from suffocation and prematurity are suggested as being related to the restrictions upon the sale of intoxicants. In an interesting paragraph Dr. Hamer discusses generally the decline in infantile mortality during recent years.

Infectious Diseases.

Two cases of small-pox were notified in London during the year, and one case of typhus. Civilian deaths from measles numbered 822, against 2,286 in 1915 and 1,376 in 1914. Throughout 1916 measles and German measles were compulsorily notifiable, and 47,470 cases in all were notified in London. Civilian cases of scarlet fever numbered 8,746, against nearly 17,000 in 1915 and 25,000 in 1914. There were fewer cases in 1916 than in any year since 1891, when notification first became compulsory. Diphtheria cases showed only a slight decrease; their number was 8,743. Whooping-cough was notifiable during the year in three London boroughs only; the total number of deaths in London from this cause was 802.

Deaths from diarrhoea and enteritis during 1916 numbered 2,009, against 3,098 in 1915 and 3,624 in 1914. Of puerperal fever, 277 cases were notified, with 158 deaths, compared with 276 cases with 132 deaths in 1915, and 393 cases with 195 deaths in 1914. The Registrar-General recorded 237 deaths from other accidents of childbirth last year, and 674 stillbirths were reported.

¹ London County Council: Report of the County Medical Officer of Health and School Medical Officer for 1916. London: P. S. King and Son, Ltd. (1s.)

The number of civilian deaths from phthisis in 1916, as well as the number of deaths from respiratory diseases generally, was lower than in 1915, but a little higher than in 1914.

Cerebro-spinal Fever.

A special section of the report deals with cerebro-spinal fever, of which 425 cases were notified among the civil population of London in 1916, a drop of 200 from the previous year. In the last two annual reports the relation between cases of cerebro-spinal fever and influenza, coughs, colds, catarrhs, etc., in epidemic and non-epidemic periods was discussed. During the past year or two this subject has received a great deal of attention from military, naval, and civilian medical officers. The inter-relation of these diseases is an interesting study. Recent work confirms Dr. Hamer in his belief that the epidemiological can no longer be subordinated to the bacteriological aspects of the problem.

The number of cases of poliomyelitis was 197, the highest on record.

Enteric Fever.

Typhoid fever receives close consideration in the report. There were 461 cases during the year, as compared with 789 in 1914 and 607 in 1915, but the figures are not strictly comparable, since the practice relating to the inclusion of military cases was not the same in 1916 as in the two preceding years. The experience of 1916 confirms that of 1915, in that evidence of a markedly increased dissemination of this disease by direct human agency was lacking. Allowing for the absence abroad of many susceptible males the prevalence of typhoid fever in London in these two years was actually lower than ever before known, despite the addition to the population of returned typhoid convalescents, and presumably also of healthy carriers from abroad. After reviewing the evidence, Dr. Hamer points out that the great decline in the prevalence during recent years has occurred *pari passu* with abandonment of consumption of shellfish and fish from polluted sources, and with removal of "layings" to a distance from sewer outfalls. He regards the classical reports of Dr. Bulstrode and the adoption of the precautionary measures outlined in them as having been very largely responsible for the great reduction in the prevalence of and mortality from typhoid fever during the last twenty years. Further care for the purity of shellfish layings and entire prohibition of ungutted flat fish are, in his opinion, the lines along which further advance can be made.

Venereal Disease.

In preparing the scheme for London under the Local Government Board venereal diseases regulations it was realized that great advantage would accrue if the local authorities adjoining the county would co-operate with the council in making use of the facilities to be afforded by the London hospitals. In the result twenty-two hospitals agreed to undertake the treatment of patients, the pathological examination of specimens, and the supply of salvarsan to authorized persons; the scheme came into operation on the first day of 1917. In a short discussion on the prevalence of syphilis in recent years Dr. Hamer sounds a note of caution concerning the interpretation of the Wassermann test, and especially with regard to estimates of widespread taint in the population based on observations of this character.

(To be continued.)

Canada.

SIR WILLIAM C. MACDONALD.

In the death of Sir William Macdonald, which occurred at Montreal on June 9th, at the ripe age of 86 years, Canada has lost one of its most generous patrons of education, and McGill University a chancellor and a benefactor who was constantly seeking to promote the interests of every department of the work of the university. Modest and unassuming in manner, austere in his way of living, Sir William was a familiar figure on the campus of the university, wandering amongst the beautiful buildings, so many of which owed their existence to his generosity—the Macdonald Engineering Building, which was burnt down

and rebuilt; the Macdonald Physics Building, the Chemistry and Mining Buildings, the McGill Union, the Macdonald Park, and the magnificent Stadium recently erected; all these remain as a permanent memorial to the munificence of one whose name will go down to history coupled with that of the Honourable James McGill, founder of the university, and Lord Strathcona, the former Chancellor. Sir William endowed various chairs in the different faculties, paid for the necessary equipment in the various departments, and over and over again came to the aid of the university. As the founder of Macdonald College—that magnificent pile of buildings on the banks of the Ottawa River, comprising a School of Agriculture, the Normal School for (Protestant) Teachers of the Province of Quebec, and a School of Household Science—Sir William Macdonald will be remembered as one who recognized the importance of agriculture in a country like Canada. In New Brunswick, Nova Scotia, and Prince Edward Island Sir William established the Macdonald Consolidated Schools as a means of improving education in rural districts. Sir William Macdonald received the honour of knighthood in 1898, and in 1914, upon the death of Lord Strathcona, became Chancellor of McGill University. His father, the Honourable Donald Macdonald, who was at one time president of the Legislative Council of Prince Edward Island, was a son of the eighth Chief of the Macdonalds.

Among the bequests made by Sir William was the sum of five hundred thousand dollars to the medical faculty of McGill University, an equal amount to the Montreal General Hospital, and one hundred thousand dollars to the Maternity Hospital.

MEDICAL LIBRARY ASSOCIATION.

The twentieth annual meeting of the Medical Library Association was held in New York on June 4th and 5th, and in Brooklyn on June 6th last. The majority of the important medical schools of the United States were represented, and in Canada the Medical Faculty of McGill University and the Academy of Medicine, Toronto. A paper on war bibliography contained a proposal to collect under subject headings medical war material.

Correspondence.

A NEW SCHOOL FOR THE STUDY OF HEART DISEASE.

SIR,—There seems to be at present a good deal of friction between the "old" and "new" school for the study of heart disease. The "new" school apparently claims that those who saw the light of day before them have made a mistake and have only felt the darkness of night. On the other hand, the "old" school apparently believes that it has not only seen the blaze of noon but bequeathed that blaze and brilliance to the juniors. My object here is to express the hope that our profession will join what for purposes of distinction I call the super-school. This term does not imply that it is a school of supermen, but it includes the other two, and will supersede them. Its aims are to benefit the patient and to attempt in every way to prevent heart disease and to guide and protect sufferers.

For fifteen years I have been urging the claims of this school, in season, and apparently chiefly out of season. Now ten days ago I received to my national sorrow and international joy a communication from New York from an association founded on these lines in 1916, with already twenty-six branches! Thus a forward step in medicine staring this country in the face for years has been taken from us, while our two schools struggle over neurogenic and myogenic theories, the action of digitalis, auricular fibrillation, and soldier's heart.—I am, etc.,

London, W., Aug. 5th.

F. JOHN POYNTON.

THE INFLUENCE OF THE WEATHER ON THE INCIDENCE OF CERTAIN INFECTIOUS DISEASES.

SIR,—Dr. Hamer, the Medical Officer of the London County Council, in his annual report for 1916, draws attention to the association between wet summers and a diminished incidence of infectious diseases, such as scarlet fever and diphtheria. This association has been frequently

remarked before, and I venture, therefore, to put forward a theory to explain it. In dry, sunny weather there is a tendency for sufferers from mild attacks of infectious disease to move about more or less freely in the open air; in other words, there is a greater chance of infected and susceptible individuals being brought into contact. During a recent epidemic of measles I have noticed several instances of this. In one case a child suffering from measles during the first week of illness was taken a daily run on the top of the tramcar, possibly as a sort of "open-air" treatment. If the weather had been wet and stormy, it is more than likely the mother would have kept the child indoors, probably in bed. In another case, where the door of the house opened directly into the living room, a child suffering from measles was found lying on a couch just within the door. Callers, such as visitors, errand and newspaper boys, milk-sellers, etc., could hardly escape contact, and the risk of contracting the disease. Moreover, all the domestic traffic in and out of the house had to pass the patient, who was placed there for coolness. If the weather had been cold and wet, the patient would certainly have been placed beside the fire, where he would have been out of the line of traffic, and the air currents would have been directly to and up the flue.

I have little doubt that similar conditions will be found influencing the spread of other infectious diseases, such as scarlet fever and diphtheria.

I suggest, therefore, that the drop in the number of cases of infectious disease reported, which so often happens after the onset of wet weather, may be in some measure attributed to the enforced home isolation which the inclement weather brings about.—I am, etc.,

Hartlepool, July 31st.

GEORGE JUBB.

THE DISCOVERER OF THE CAUSE OF SLEEPING SICKNESS.

SIR,—I have just read a paper in your issue of July 28th on "Tropical medicine and research," by Sir Patrick Manson. In the section on trypanosomiasis he writes:

Later, Castellani, also a former student of the London School of Tropical Medicine, and at the time a member of the Royal Society's Commission for the study of sleeping sickness in Uganda, found the same parasite in the cerebro-spinal fluid of patients suffering from sleeping sickness. Sir David Bruce, Nabarro, and many others, confirmed Castellani's observation, and definitely linked up the trypanosome of Forde and Dutton with sleeping sickness as cause and effect.

This means to the ordinary English reader that Castellani was the discoverer of the cause of sleeping sickness, and that Bruce, Nabarro, and many others merely confirmed his observation. I thought this controversy had been finally disposed of in 1913, but if so well known an authority on tropical diseases as Sir Patrick Manson still erroneously attributes this discovery to Castellani, I feel it to be my duty as Chairman of the Sleeping Sickness Committee of the Royal Society in 1903 to again intervene. In a letter to the *Times*, August 14th, 1913, I wrote:

There is no possibility of doubt that the demonstration of trypanosomes as the parasitic cause of sleeping sickness was made solely by Sir David Bruce, and that Castellani, although he had seen these parasites at Entebbe, definitely stated on the day of the arrival of Bruce at that place that he did not consider them to be of any importance as regards sleeping sickness.

This matter was thoroughly discussed in the *Times*, when Castellani put forward his claims in 1908 to the honour of this discovery. His claims were shown by the overwhelming testimony of those who had been with him at Entebbe to be baseless. The "Sleeping Sickness Committee" of the Royal Society specially investigated the matter, and Colonel Bruce reported to that Committee as follows:

For the sake of the future historian it may be well to point out the exact state of affairs as regards our knowledge of sleeping sickness in relation to trypanosomes when Colonel Bruce arrived in Entebbe on March 16th, 1903.

Dr. Castellani had observed these haematozoa in the cerebro-spinal fluid of five cases of sleeping sickness, and in one of these he had also seen them in the blood.

At the time of the arrival of the Commission (i.e., Colonel Bruce) Castellani did not consider that this trypanosome had any causal relationship to the disease, but thought it was an accidental concomitant like *Filaria perstans*.

Upon this statement the Committee (of which I was chairman) made and signed the following minute, which is

now preserved in the minute-book at the Royal Society's offices:

November 26th, 1903. That the statements in Colonel Bruce's report correctly and fairly represent the facts, and do full justice to the part played by Dr. Castellani in the investigation.

This was signed among others by Sir Patrick Manson himself. I am unwilling to encroach on your valuable space, which I know to be greatly restricted at present, so I shall only refer any of your readers who may be interested in this matter to the letters which appeared in the *Times* from Sir John Kirk, Dr. Moffat, P.M.O. of Uganda, Dr. Baker of Uganda, myself, and others.

If I may be permitted to do so, I should like further to draw attention to a statement made by Major R. McCarrison in a paper entitled "India and medical progress," which appeared in the same issue of your *JOURNAL*. Regarding Ross's discovery in 1898, that bird malaria is conveyed from bird to bird by the mosquito, he writes:

Through it a great light was shed upon the mode of spread by suctorial insects of other protozoal diseases, by which light the problems of the propagation of dengue, yellow fever, sleeping sickness, and other diseases of the tropics have reached, or are gradually reaching, solution.

Surely the boot is on the other leg. It was the discovery by Bruce in 1895 of the rôle played by the tsetse fly in the propagation of trypanosome disease which led to the discovery of the part played by the mosquito in malaria.—I am, etc.,

London, S.W., July 30th.

E. RAY LANKESTER.

THE NEEDED MEDICAL MEMBER OF THE SECRETARY OF STATE FOR INDIA'S COUNCIL AT WHITEHALL.

SIR,—I propose that the Secretary of State for India nominates to his council in London a member of the Indian Medical Service who holds, or has held, a seat on one of the Indian provincial Government councils, and who is specialized in administrative work and sanitary knowledge. No such adviser now exists. The very able President of the Medical Board at the India Office is completely employed in dealing with the medical examinations at the India Office, but it is an official acquainted with administrative work in India who is needed to advise the Secretary of State for India. Such an official would keep touch with the progress of sanitary administration in England, would watch the action of the English Local Government Board in all health matters, and would be in touch with the Director General of the Army Medical Service at the War Office. I cannot imagine how a Secretary of State for India can fulfil his responsibility without such an official on his council. The few thousand pounds this addition to the council would cost in salary, clerks, and office staff would amply repay India for her money so expended. Why such an appointment was not created years ago is an outward and visible mark of the defective medical organization in Indian official life.—I am, etc.,

GEORGE J. H. EVATT, M.D.,
Surgeon-General A.M.S.(ret.).

Junior United Service Club,
London, S.W., July 28th.

QUO VADIS?

SIR,—No doubt I shall broaden Dr. Wood's smile when I marvel at his "knowledge" whereby he assesses the value of proofs and witnesses unheard and unseen by him. One rather thinks that a good deal of mistaken diagnosis is founded upon similar knowledge.

The "main point" of my letter was that an assertion was made by the chairman of the practitioners' meeting referred to therein, and that the assertion was challenged by Dr. Wood. As a member of the meeting I have confirmed the assertion. It need only be added that the evidence and witness were sufficient to carry weight with a roomful of ordinary mortals not possessing Dr. Wood's remarkable intuition. Of course, the fact he cites was duly taken into consideration, together with all other known facts, and our judgement formed upon the weight of evidence. I withdraw nothing from, and qualify nothing in, my previous letter, and readers who are sufficiently interested may be left to draw their own conclusions.

As regards the number of men the Government had at the time "ready to go anywhere," any estimate is only

based upon surmise; but it is no surmise to say that that number would have been augmented, had occasion required, by many more hundreds. And so long as the fifth paragraph of Dr. Ogilvie's letter on p. 165 of the JOURNAL remains a statement of fact, as it assuredly is, so long will the truth of my letter be, unfortunately, beyond question.—I am, etc.,

Histon, Aug. 4th.

L. GWILLIM DAVIES.

SIR,—In the JOURNAL of July 14th Dr. Rawdon Wood wrote that as a "farewell" to medical politics he "must nail to the counter" my statement that in 1912 the Government had a whole-time service scheme and were prepared to work it. In plain English, that was, in his opinion, an erroneous statement. I am not concerned with Dr. Wood's estimate of my reputation for accuracy, but when the official JOURNAL comments with favour on the "aptness" of Dr. Wood's comparison with the Russian legend in support of his contention some notice must be taken of it.

Dr. Wood must be singularly ill-informed of the history of the Insurance Act developments in 1912 if he is unaware that in October of that year the Chancellor was in a position to state (1) that in many districts the medical men were prepared to accept improved terms of remuneration rather than risk a whole-time service; and (2) wherever else the local profession might continue to resist, a whole-time service would be instituted, he having at that date already large numbers of well-qualified applicants for prospective appointments. These statements were accepted as incontrovertible by leaders of the profession, and no doubt influenced them in the advice they proffered to the ranks concerned. Further, the acceptance was reflected in the absurd advice of the Representative Body to make terms if possible with the clubs, thereby abandoning one of the six cardinal points of our policy. The Council failed to maintain the resistance which the "pledges" were intended to guarantee, and from that hour discipline, if it ever existed, was at an end. This deplorable incapacity of the profession to unite and to make its influence felt in the shaping of public health legislation will be seen again shortly unless the Association, as the only representative body, can exert its latent powers in a worthy manner.

I have nothing to fear from what the officials of the Association may disclose if Dr. Wood's demand for publication of the evidence were met. It would be surprising if all the material facts were to see the light, and, even so, it would be difficult to reproduce the run of the cards at any given moment during that crafty game of 1912. But Dr. Wood and others might learn for the first time something of "the windings of political intrigue" to which I referred in my previous letter, and he might find his satisfaction in bidding "farewell to medical politics" considerably enhanced.—I am, etc.,

Cambridge, August 6th.

B. E. FORDYCE.

A STATE MEDICAL SERVICE.

SIR,—My article in the *Westminster Gazette*¹ was almost entirely devoted to an attempt to sketch the advantages of such a service to the nation; a great part of the replies is devoted to proving what I never doubted or denied, namely, that the medical profession is generally opposed to it. I candidly admitted that fact. Such views as I have occasionally heard in favour of it have come not from young but from middle-aged practitioners in the services. But the opinion of the profession is naturally conservative, and is not the vital factor of the question.

The main issue is this: Would such a service be a benefit to the nation? If that can be proved, then, as the natural guardians of the nation's health, we must sink our individual preferences and acquiesce. There can be no other possible course. We only stand on a special footing, and our views will only be specially considered because in any change the status of the profession, and the attraction it offers to the best brains, must be raised instead of lowered. A lowered standard of professional life would be a national calamity.

Some of those who oppose any change fail, if I may say so, to realize the situation as it exists to-day. A State service is referred to as some remote and impossible contingency. Are we not actually in danger of having a State

service forced on us piecemeal under conditions that satisfy no one, and possess the double disadvantages of both public and private service? Personally, I should prefer a change, if it were to come, at one mouthful, under my conditions, than in a succession of nibbles under some one else's conditions, and we are travelling in that direction to-day.

The treatment of infectious disease, of mental cases, of paupers, is already largely out of the hands of the private practitioner. Venereal disease threatens to come under the same category, and so does tuberculosis.

Again, what is the Insurance Act which we bitterly but unsuccessfully opposed, and which deals with the medical needs of about one-third of the population, but a modified State service? It makes no difference whether an Insurance Committee or a State department stands between doctor and patient; the intervention is there all the same. The direct, intimate, personal relation between doctor and patient is overshadowed by some third party who controls the purse strings. This was one of the strongest arguments brought against the Insurance Act. Therefore I suggest we are swallowing a State service piecemeal. A Ministry of Health may contain other limitations of private practice too.

Let us be prepared with a satisfactory scheme lest one day we are again caught unawares, and presented with a *fait accompli*.—I am, etc.,

August 1st.

THE WRITER OF THE ARTICLE.

* * * Our correspondent has not advanced his argument that a whole-time salaried State medical service would be a benefit to the nation.

THE CONSTITUTION OF A MINISTRY OF HEALTH.

SIR,—These are anxious times for those who love our profession, which is having the greatest struggle in its history for its very existence as an art and science, free and untrammelled to do always that which is right and without fear or favour. If our independence is lost, as we all hope and trust it may not be, it will not be from any fault of yours in warning us of what our apathy will lead us to. Over and over again you have pointed out that the thirty-four thousand doctors in the United Kingdom are not taking their rightful place in the councils of the nation or even in those matters of which they alone have made a long and special study. Every county council should have two or three medical men in it. And the proposed Ministry of Health should not only have a Doctor of Medicine at the head of it, but all the subchiefs and principal employees should be doctors. No one is so qualified as the doctor who spends his days and sometimes half his nights among the poor to know what the poor require to make their health better. The doctors of Great Britain have been saving 100,000 babies' lives every year for fifty years and they could save a hundred thousand more if they had the means provided to obtain milk. Profiteering in milk does not save babies' lives, and if the proposed Ministry of Health were manned by doctors from top to bottom the first thing they would do to save infant life would be to provide the necessities of child life at or nearly at cost price instead of allowing the price to be made prohibitive as it is, and they would see to the housing of the poor.

Some do not think, judging by your correspondence, that it would be right to settle such an important matter, and one having so great a bearing upon the future of our profession, as the Ministry of Health, at a time like the present, when ten thousand doctors are away with the forces fighting for our hearths and homes. I rather agree with those who think the time is not propitious. But in any case the head of such a ministry must not only be a doctor, but he must be one elected from the rank and file of the profession who have had long and active practice in the homes of the poor. He must have the confidence of the thirty-four thousand medical men with whom he has to deal, and whose help and sympathy are absolutely necessary to make the Ministry a success. The only reasonable way in which to find such a man is to elect him, and such an election could be held as soon as voting papers could be sent to every registered medical man and woman. These voting papers, numbered and sealed, could be sent by registered mail, and could contain

¹ See BRITISH MEDICAL JOURNAL, July 14th, p. 55.

a registered return envelope. The voters would enter on them the names of the three most suitable men for a Minister of Health. The thirty having the largest number of votes could meet in London soon after, and elect from their number the very best man for the position. The subchiefs could be chosen from the remainder. There may be some other and better way, and, if so, we should hear about it now. Such a Minister of Health would soon set the machinery in motion for the betterment of the health of the nation. He knows already, as do most of the thirty-four thousand doctors, what is needed, and every month he could gather in council around him the county medical officers from all over the country who are recognized as the ablest health experts in the three kingdoms.

A Ministry of Health composed entirely of doctors would know how to treat the thirty-four thousand most highly educated men in the community in such a manner as soon to remove the many causes of unrest and distrust which are only too evident to any one reading the letters from your correspondents.

In many countries the President of the Republic is a doctor, while in others a doctor is Prime Minister, while in almost all doctors are either Ministers or members of parliament. In all other countries as far as I know all legislation concerning the health of the nation emanates from one source alone, and that is from the national medical association. Our British Medical Association is quite able and I believe willing to undertake the organization of a Ministry of Health, and no more important meeting could ever be held than a three days' session in London this autumn for this purpose.

All this bears out the importance of medical men taking a greater interest in national affairs, as you have so frequently and forcefully pointed out. For your efforts in this direction I shall always be—

July 25th.

A. CONSTANT READER.

DR. ADAMI'S CROONIAN LECTURES.

SIR,—It is a piteous exhibition that Sir Ray Lankester has made of himself, and were it not that he has again touched upon points of personal honour I would have preferred to be silent and not further discover his shame. But by his deliberate misrepresentations and reiterated and unfair attempts to place me in the wrong, he has left me no option. He forces me to point out:

1. That he repeats and does not withdraw his accusation "that Dr. Adami erroneously claimed novelty for the view that the activities of the bacteria are susceptible of change under changed environment." I made no such claim. On the contrary, I called attention to the fact that Pasteur, Roux, and Chamberland had demonstrated changes of this order. It was not necessary for me to inform my audience that the demonstration was afforded in the early Eighties, or that Pasteur died before this century opened. What I did claim was that "the latter day investigations in medical science" showed that certain of the above-mentioned changes were of the nature of direct adaptation, or direct equilibration—a very different matter.

2. That he repeats the charge that I misapprehend the significance of the word "adaptation," and states that I admit the blunder. Far from making any such admission, I, on the contrary, proved to the hilt, by a reference to Herbert Spencer's own words, that the misapprehension was his, that my use of the term was consistent and correct, and that it was he and not I who misused it. He must himself admit, now that the heat of the moment has passed, that this is not clean fighting. It is inexcusable.

3. That as for his repetition of the charge of an offence against the laws of social intercourse by making use of a confidential communication, I must point out, in fuller detail than in my last, that it was Sir Ray Lankester himself who, while knowing my address, by transmitting his letter, addressed to me, to a third person for prior perusal, converted what would otherwise have been a private into an open correspondence. I have his letter of transmission before me as I write. It may interest him to know that previous to the delivery of my first lecture I put the case before two friends of his, both men of distinction, one of them a Fellow of the Royal College of Physicians. Both held that I would be justified in referring to the correspondence, and this, in the case of one of the two,

after he had read the manuscript and seen the exact terms of the reference.

It will be observed that Sir Ray Lankester takes no notice of my challenge that he should publish this earlier correspondence and prove that I had, as he asserted, "garbled" my reference to his views. He cannot afford to refuse to discuss so vital a matter as this of the evidence recently obtained regarding direct adaptation with its bearing upon heredity and social matters of the first order. He cannot do this without tacitly resigning his position as a leader. To preserve his own honour I again ask him to publish the triangular correspondence already referred to, that the points at issue may be clearly defined.

Surely I need say no more.—I am, etc.,

London, W., Aug. 6th.

J. G. ADAMI.

PAYMENT OF MEDICAL OFFICERS TO V.A.D. HOSPITALS.

SIR,—As regards auxiliary hospitals which have set apart beds for wounded soldiers, it appears to me that if the medical attendants have no pay it is their own fault.

In August, 1915, I wrote to Dr. Cox on the subject, and received full information and courteous replies from Mr. Bishop Harman and Dr. Cox, as secretaries of the War Emergency Committee. The staff of our hospital was granted payment by the War Office for any number of soldiers when more than twenty beds were occupied. When I saw that payment was given at another local hospital, the obvious thing to me was to make inquiry.—I am, etc.,

Loughborough, Aug. 6th.

J. B. PIKE.

MEDIUMISTIC METHODS.

SIR,—I have examined a few reports of sittings with "mediums," and by comparing them have formed the opinion that by the examination of a larger number a definite and convincing exposure of their methods could be compiled. They are mainly stereotyped in their matter, but a considerable number is necessary to demonstrate this conclusively. They are doing much harm by the suggestion of hallucinations through expectant attention, and in other ways.

If any of your readers could induce patients or friends who have such reports to lend them to me, in strict confidence, I should be greatly obliged.—I am, etc.,

HENRY RAYNER.

Upper Terrace House, Hampstead, N.W.3.
Aug. 2nd.

Obituary.

HERBERT FRANCIS HAYES NEWINGTON,

F.R.C.S. EDIN., M.R.C.S. ENG.

THE death of Dr. H. F. Hayes Newington, of Ticehurst, must have come as a painful surprise to the numerous friends who had seen him taking an active part in the proceedings of the annual meeting of the Medico-Psychological Association a few days previously. Dr. Newington had been so long and so intimately connected in so many ways with that association that it would seem appropriate that his latest piece of public work should have been in connexion with it. His admirable and successful work as treasurer, great as it was, is but a small part of the able and ungrudging services that he had rendered during the past forty years. During the fourteen years preceding the passing of the existing Lunacy Acts, almost yearly bills had to be considered and discussed, and often combated through friendly members in the House of Commons; in all these efforts Hayes Newington took a leading part. He also organized the resistance of those interested in private asylums against the legislative dangers with which they were threatened. His services on the Parliamentary Committee, of which he was chairman for many years, cannot be too highly estimated, and his work on the Educational Committee, to which so much of the improved character and status of the nurses of mental hospitals is so largely due, was also of the highest value.

Hayes Newington was a member of a medical family that has for generations conducted an establishment for the treatment of mental diseases at Ticehurst in Sussex.

After completing his medical education at King's College Hospital, he served for some years as a medical officer in the Royal Edinburgh Asylum, rising to the position of senior assistant physician. With this experience he became physician of the Ticehurst institution already mentioned; he was part proprietor, and superintended it with eminent success. His contributions to alienistic literature have been of considerable extent; in addition to his address as President of the Medico-Psychological Association in 1889, the articles on "Stupor" and on "Some mental aspects of music" testify to his originality of thought. His clinical acumen is evidenced in "Hemiplegia in relation to insanity" and in many other papers in the *Journal of Medical Science*.

Dr. Hayes Newington was an old member of the British Medical Association, and was vice-president of the Section of Psychology at the annual meeting of the Association in Edinburgh in 1898. He was also a representative of the Medico-Psychological Association on the special sub-committee on incipient insanity appointed by the Parliamentary Bills Committee of the British Medical Association in 1900, and in subsequent years rendered great assistance to the Medico-Political Committee of the Association in connexion with the amendment of the law with regard to the treatment and detention of cases of incipient insanity, inebriety, and the drug habit.

Dr. Newington played a very active part in local affairs, especially as county councillor for East Sussex, taking great interest in the planning of the latest Sussex Asylum, of whose committee he was an esteemed and valued member.

Apart from medical and social work he was a skilled musician, a keen gardener, and excelled, thanks to his fine physique and calm temperament, in many games and sports. In all the varied relations of his life he was a typical example of the humane physician and of the English gentleman. His genial manner and invariable consideration for others, together with his absolute fair-mindedness, won him many and sincere friends who will long regret his loss.

He leaves a wife, a daughter, and a son who has distinguished himself in the present war.

Dr. CHARLES MERCIER sends us the following appreciation:

The announcement of the death of my old and valued friend, Hayes Newington, is a heavy blow. Only last week we were engaged in one of those wordy combats of which we had so many, which left our warm friendship unimpaired, and indeed strengthened, for they were usually accompanied by a private interchange of chaffing letters. Hayes Newington was a Tory both in politics and in medicine. He would have said, like the late Duke of Cambridge, that he was ready to welcome any innovation that was an improvement; but, like the late Duke, he never considered an innovation an improvement. He was nevertheless a sound physician, and there was no man to whom I entrusted a patient with more confidence. His attitude towards the insane was peculiar. He looked upon himself, not only as their physician, but beyond this, and even more than this, as their guardian. Every measure concerning the insane may be looked on from at least two aspects: It may be regarded from the point of view of the community, and judged according as it is better or worse for the community; or it may be looked on as affecting the madman, and as better or worse for him. It was from the latter point of view almost exclusively that Hayes Newington regarded a measure. Sir Thomas Clouston once divulged in an outburst of candour that the insane are "unloveable." He might have used a stronger term, and still expressed what most of us feel. Their disease removes the higher qualities of their nature, and leaves the lower outstanding in their naked repulsiveness. But Hayes Newington never allowed himself to think of them or to speak of them thus. The manifestations of the lower nature, which are repulsive to most of us, did not repel him. He looked upon them with a mild and admirable toleration, as the manifestations of disease, and he never went further in antagonism than to view them with amusement. He was a good organizer and a wise counsellor. He took over the Treasury of the Medico-Psychological Association when the fortunes of that body were at a low ebb, and he lifted it into a position of

prosperity and influence which few of its members expected it would ever attain. He guided its counsels for many years, and he will be as much missed in that association as he will be at Ticehurst. He had the satisfaction of knowing how highly his great services were appreciated, for the association presented him with his portrait. Though he was 70, none of us looked upon him as an old man, and he has died as an active, hard-working, and wise man would wish to die, with no preliminary period of decay. He will be long had in affectionate remembrance, for no man can quite fill his place.

Dr. J. F. BRISCOE (Boscombe) writes: As a physician of one of the largest private mental hospitals Dr. Hayes Newington practised his art with consummate skill, and set an example in the management and care of institutions for the well-to-do insane. Such private hospitals for the insane are greatly needed at the present moment, and those who minister to the welfare of the inmates deserve every consideration from the profession. The life is filled with care and anxiety, though mistrust of these private mental hospitals, vulgarly called private asylums, is long since forgotten, since they are not only governed by statutory formulas, but have the immediate eye of that beneficial commission, the Board of Control.

Dr. THOMAS BROWN DARLING, of Morningside, Edinburgh, passed suddenly away on July 29th, whilst attending divine service in Alvey Church, Aviemore, where he was spending a few days of well-merited rest. It is only a few months since he was called upon to mourn the loss of his second wife. Dr. Darling was the son of Mr. Darling, the founder of the Regent Hotel, an early and a well-managed establishment on temperance principles; and he himself took a constant interest in the cause, being treasurer of the Edinburgh branch of the British Medical Temperance Association. Dr. Darling graduated M.B., C.M. in 1884, and became M.D. in 1890. He acted as resident surgeon in the Royal Infirmary and at the Edinburgh Royal Maternity Hospital in the winter of 1884-5, and was a member of various medical societies in Edinburgh. He settled in the Morningside district of Edinburgh, and there for some thirty years he had a large practice and was widely esteemed and beloved. A great and prevailing cheerfulness, combined with real personal sympathy and understanding, marked all his dealings with those under his care. He is survived by a son and two daughters, the former being on active service in the R.A.M.C. From time to time he made interesting contributions to the medical journals, although he was pre-eminently a practitioner rather than a writer.

Dr. JAMES RUSSELL, who died at Hamilton, in the Province of Ontario, Canada, enjoyed a wide reputation as an alienist. He was for many years superintendent of the Hamilton Asylum, and a member—and at one time president—of the American Medico-Psychological Society. He was also a member of the Ontario Medical Council. He was born in Lanarkshire, Scotland, in 1843, and went to Canada as a boy of 13. His medical studies were made in New York and at Toronto University, where he graduated in 1869. He spent some years as a general practitioner in Hamilton, and in 1887 was appointed superintendent of the Asylum, a post for which his administrative ability made him eminently fitted.

Dr. FRÉDÉRIC LABADIE-LAGRAVE, sometime physician to the Maternité and afterwards to the Charité Hospital, Paris, died recently at the age of 73. He studied at Paris, took his doctor's degree in 1873, and was appointed physician to the Paris hospitals in 1879. In conjunction with Germain Sée he published a work on clinical medicine in twenty volumes, to which he contributed treatises on urology and diseases of the kidney, and on diseases of the liver and bile ducts. He was the author of a medico-surgical treatise on gynaecology, written in conjunction with Professor Leguen, which had a great success. He also contributed several important articles to Jaccoud's *Dictionnaire de Médecine*. While he was still interne he served in the war of 1870, and was decorated on the battlefield at Metz for guiding and saving a large convoy of munitions and provisions. Dr. Labadie-Lagrave retired from active practice in 1909.

Universities and Colleges.

UNIVERSITY OF LONDON.

A meeting of the Senate was held on July 18th.

The annual report by Dr. L. Mellanby, acting superintendent of the Brown Animal Sanatory Institution, stated that 3,769 animals, including 2,237 dogs, 1,130 cats, and 225 horses, had been brought to the institution during the year. A portion of the assistant superintendent's work on experimental rickets, undertaken at the request of the Medical Research Committee, had been carried out in the laboratory of the institution.

Miss Janet E. Lane-Caypen, M.D., has been appointed a member of the National Council for Domestic Studies.

Dr. S. Russell Wells, Sir Rickman Godlee, and Mr. H. J. Waring, M.S., have been elected Chairman of the Council for External Students, the Brown Animal Sanatory Institution Committee, and the Dixon Fund Committee respectively.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

At a special meeting of the President, Vice-President, and Council, Lieut.-Colonel William Taylor, President, in the chair, Major Francis Carmichael Purser, M.D., L.R.C.S.I., was unanimously elected Professor of the Theory and Practice of Physic in the Schools of Surgery.

Medical News.

Dr. A. LINNELL of Paulerspury has been elected vice-chairman of the Northamptonshire Insurance Committee.

THE King has granted permission to the following to wear the decorations indicated conferred upon them by the Sultan of Egypt in recognition of valuable services rendered by them:—*Third Class of the Order of the Nile*: Dr. Reginald G. Kirton, P.M.O., Prisons Department, Cairo; Dr. William F. C. MacCarthy Morrogh, President of the Central Medical Commission, Public Health Department, Cairo. *Fourth Class of the Order of the Nile*: Dr. William C. Hayward, Inspector, Public Health Department, Cairo.

THE Rockefeller Foundation is about to build two hospitals in China—one at Peking, the other in Shanghai—at an estimated cost of £600,000. The Foundation has also decided to send a hospital ship to the Moros and allied tribes of the Sulu Archipelago; it will cruise for five years among the islands in the Southern Philippine group. Skin diseases, malaria, hookworm, dysentery, and other affections are rife among the Moros. The Philippine Government is co-operating in the enterprise.

THE annual report for 1916 of the Saint Paul's Hospital for Skin and Genito-Urinary Diseases, Red Lion Square, London, W.C., states that it is one of the approved centres for the treatment of venereal diseases in London. It is one of the four which at the suggestion of the National Council gives free early treatment to soldiers thereby involved, and to be prepared for after-war conditions. The committee has leased, adapted, and equipped part of the adjoining premises, and provided additional beds for venereal patients. An appeal is made for funds to defray the cost of these extensions.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Antiology, Strand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate, Strand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Mediscera, Strand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

QUERIES.

INCOME TAX.

D. T. W. has been in charge of a military hospital at a salary of £1 ls. a day for two years as a civil medical practitioner, and has included that remuneration in his general income tax return. The local surveyor of taxes says that the special (military) rate of tax does not apply to "D. T. W.'s" remuneration, and he asks what steps should be taken to have this opinion set aside.

*. Seeing that our correspondent is paid by the War Office as a temporary civilian practitioner the point is not free from

doubt, though his services would seem to be of a military character. In the circumstances we suggest that the full facts be placed before the Board of Inland Revenue for their ruling on the point before any further steps be taken.

LETTERS, NOTES, ETC.

RINGWORM IN ADULTS.

THE note on small-spored ringworm of the scalp in an adult, by Dr. Henry Waldo, published in the JOURNAL of July 21st, p. 81, has brought us other communications. The interest lies in the occurrence of the condition in an adult, for both the small-spored and the large-spored variety produce a disease which is clinically ringworm. Dr. Norman Walker, in his *Introduction to Dermatology*, states that in Scotland most of the cases are caused by the small-spored variety. In London the proportion is between 80 per cent. and 90 per cent., and in Paris 60 to 70 per cent.; while in Italy nearly all the cases are due to the large-spored variety.

DR. G. H. LANCASHIRE (Manchester) writes to state that four years ago he saw a woman, aged 23, who had on the scalp a typical patch of microsporon ringworm, the size of a shilling; the diagnosis was confirmed by microscopical examination. The only feature distinguishing this case from ordinary juvenile scalp ringworm was the rapidity of the cure, which took place within a few weeks, under oleate of mercury ointment. This being the only case of the kind he had seen amongst multitudinous examples of ringworm, Dr. Lancashire is still of the opinion that, in that district, scalp ringworm might be practically regarded as a disease of childhood.

DR. D. OWEN WILLIAMS (Glandyfi, Cardiganshire) writes that he saw recently a case of ringworm in a seaman aged about 35. There were large patches measuring 5 in. each on the sole of each foot and also lesser patches on the legs. They cleared up rapidly under the treatment for tinea tonsurans which he adopted. He had recently also a case of ringworm of the scalp, at the junction of the skin and the hair, in a youth of 17, which has now cleared up.

A CLINICAL TEST FOR THE ESTIMATION OF THE PERCENTAGE OF GLUCOSE.

DR. J. BARKER SMITH, L.R.C.P. (Herne Hill, S.E.) writes: As a worker using colour methods for quantitative estimation of glucose, ammonia, nitrates, etc., during twenty years, and having for ten years ceased to use my chemical method of delivering definite solution of acid permanganate into weak solution of potassium iodide in favour of coloured glasses, I am interested in Mr. Parnell's letter in the BRITISH MEDICAL JOURNAL of June 23rd, p. 842. I have always felt we required colour standards fixed for the whole profession to use for reference. I began my use of colour glasses regretting that we had no definite standards for colour, especially for the colour of urine—normal, jaundiced, caramelized, etc. Taking a normal of ammonia in urine as 0.03 per cent., I fixed approximately unit one of my colour glasses on this normal of ammonia when the urine is diluted to a thousand, using 25 c.cm. of the dilution, 1 c.cm. of Nessler's solution, and waiting one minute. Such unit approximates to the colour of the "pale yellow" of our textbooks on urine, or a pale chip box. I found caramelization afforded means of estimating the minute quantities of sugar in cereals, by colour or by oxidation (*The Miller*, 1894, serial articles). I examined Mr. Parnell's glasses some years ago, and note in my work book that, using the test which he describes, a ½ per cent. of glucose would be nine units on my scale, a 1 per cent. sixteen units. I use a test tube of water as a background for the glasses. We want common standards.

FULLY PROTECTED.

A CORRESPONDENT asserts that the following story is true in fact: A few weeks ago a medical officer made the tour of the large general hospitals in Alexandria in order to determine what percentage of the patients had been inoculated against typhoid fever and against typhoid, paratyphoid A and paratyphoid B (T.A.B.). This information ought to be recorded in each man's pay-book, but one man had no pay-book with him, so he had to be cross-questioned. He said, "Yes, sir, I have been inoculated against pretty well everything—about nine times altogether. The last time, I remember, it was against V.A.D."

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

THE PART PLAYED BY BRITISH MEDICAL WOMEN IN THE WAR.

BY

MISS MARY H. FRANCES IVENS, M.B., M.S.LOND.,

SURGEON-IN-CHARGE SCOTTISH WOMEN'S HOSPITAL,
ROYAUMONT, FRANCE.

In the days of peace medical women took their share in all phases of professional life in Great Britain and Ireland so that they needed no separate history. But in war the spheres of work open to them are limited by military considerations, and it has seemed proper, therefore, to attempt some account of the manner in which they have come forward to render professional services to the wounded and sick. They have not shrunk from personal risk and hardship, and at the same time have done their part in bringing modern scientific methods to bear on the novel clinical problems with which the special circumstances of this war have confronted military medicine, and have not only individually shown untiring energy in emergencies, but also an admirable capacity of a combination and organization in face of unforeseen difficulties. The account does not profess to be complete, it does not make mention of much good work done by individuals, and contains little reference to the many medical women who have laboured with medical men at home for the good of the civil population; but such as it is it has an interest of its own as a sketch of the work done by British medical women in the first war in which they have been numerous enough to count.

In the early days of the war British medical women volunteered their services in aid of the wounded of their own country, but finding that the British Red Cross and the War Office were at that time amply supplied, they turned their attention to the needs of the Allies, whose countries were already invaded by the enemy. Units composed partly or entirely of women were accepted for service under the Belgian, French, and Serbian Red Cross.

The Women's Imperial Service League was the first to send a hospital to Belgium, and though, owing to the rapid and unfortunate march of events there, its career was short, it rendered very material service during the siege of Antwerp. Miss Stoney, M.B., B.S.Lond., with a staff of six women doctors, was in charge of the hospital, which was full of seriously wounded cases when the bombardment on October 8th took place. The hospital was eighteen hours under shell fire before the patients (Belgians and some British) could be placed in comparative safety. During this time no member of the unit was injured, although the ground was littered with shell and the houses round were burning. The unit crossed the Scheldt by the bridge of boats on London motor buses to join the retreating British marines twenty minutes before the boats were blown up by the retreating Belgians.

In November, 1914, the unit was formed again, and a hospital of 70 beds was established at Cherbourg under the French Red Cross in an ancient chateau. Two days after their arrival seriously wounded French, Belgians, and Senegalese came in from Dunkirk by boat. Most of the cases had badly comminuted fractures, and, as they did not arrive until four to eight days after being wounded, a considerable number of amputations had to be performed for gangrene, advanced sepsis, septicaemia, and secondary haemorrhage.

It was not until the spring of 1915 that medical women undertook the full charge of British wounded in England, although in October, 1914, Dr. Louisa Garrett Anderson established, under the French Red Cross, a small hospital in Paris which received some British wounded.

In consequence of a rearrangement of the transport of the wounded the hospital at Cherbourg was closed early in 1915. Dr. Florence Stoney was appointed radiologist to the Fulham Military Hospital in April of that year, with a ward for the treatment of cases of disordered action of the heart, shell shock, and Graves's disease. By January, 1916, this department had already examined 4,351 cases, and had taken 5,530 skiagrams, in addition to giving *x* ray, high frequency treatment, and vibratory massage. The

special study of the action of *x* rays in hyperthyroidism led Dr. Stoney to point out the close connexion between hyperactivity of the thyroid gland and the tachycardia and breathlessness seen in cases of "irritable heart" and "soldier's heart." By *x*-ray treatment the thyroid gland can be reduced in size. As it grows smaller the symptoms disappear. The thyroid in exophthalmic goitre is much more easily affected by *x* rays than the thyroid of a quiescent bronchocele, as the glandular cells are in a very active condition. Conditions similar to Graves's disease are produced by war strain. Dr. Stoney believes that *x* rays are a specific for exophthalmic goitre, though the heart condition is incurable, the muscle remaining weak, so that the organ can be more easily overstrained than a healthy heart. Symptoms of hyperthyroidism are often of late onset in ordinary bronchocele, when microscopically areas of altered tissue similar to that occurring in exophthalmic goitre are found. Thus Graves's disease may be primary (most of the cases in the war come under this group), or grafted on to a pre-existing bronchocele. Dr. Stoney places special stress on the following abnormal symptoms needing treatment: (1) Fine tremor, (2) excessive perspiration, (3) great nervousness and twitchings, and (4) a pulse-rate habitually over 90. A common combination is tremors, breathlessness, tachycardia, weakness, and sweating, nervous twitchings, and obliteration of wrinkles on the forehead. Though *x*-ray treatment does not deal with the primary cause of the disease it relieves the patient by lessening the thyroid gland. Its chief disadvantage is that several sittings, spread over a couple of months or more, are required. *X* rays are applied as vigorously as is compatible with safety. One Sabouraud dose filtered through one or two millimetres of aluminium is given to each side of the thyroid weekly in about twenty minutes. The heart is one of the earliest organs to respond, becoming regular and of normal size. After some time exophthalmos usually disappears and the goitre diminishes. The only risk is that of temporary pigmentation of the skin occasionally going on to telangiectasis.

Scottish Women's Hospitals.

In September, 1914, an Edinburgh graduate, Dr. Elsie Inglis, was instrumental in promoting the formation of the Scottish Women's Hospitals for foreign service, and units consisting entirely of women were arranged for Belgium, France, and Serbia. The first unit, intended for Belgium, was, owing to the German occupation of that country, sent to Calais. It was not a complete unit, but consisted of a staff of doctors and ten nurses under Dr. Alice Hutchinson. It worked during the severe typhoid epidemic among the Belgian soldiers under Dr. Depage from November, 1914, to April, 1915; the mortality among its patients was relatively low.

Work in France.
